Clinical Lecture on ATAXIC PARAPLEGIA.

Delivered at University College Hospital, Feb. 23rd, 1886,

By W. R. GOWERS, M.D., F.R.C.P.,
ASSISTANT PROFESSOR OF CLINICAL MEDICINE.

GENTLEMEN,—As a definite name for a definite disease the term "ataxic paraplegia" is doubtless unfamiliar to you. It is probable, however, that in the course of your clinical work, especially in the out-patient room, you have met with examples of the malady, and it is not improbable that you have been puzzled by its somewhat anomalous features. The disease is, indeed, by no means rare. It is a somewhat common form of chronic [illegible]sy of the legs. We have now in the wards two well-marked cases, which afford us a good [illegible] of its characters and course. Although it is not [illegible], you will find little about it in text-books. In [illegible]s of general medicine you will probably find no [illegible] works on diseases of the nervous system you may [illegible] some mention of it as the manifestation of combined sclerosis of the lateral and posterior columns, perhaps as a variety of locomotor ataxy or of spastic paraplegia. But the manifestations of the disease are so definite that it deserves separate description. The account I am about to give you is founded chiefly on a series of cases that have come under my own observation, of which the symptoms were uniform and characteristic. We shall see that there are reasons which make it desirable to call it by a name that is founded on its clinical characters, rather than on the pathological lesion that underlies these characters.

Of the two cases that are before you one is a man and the other is a woman. Thus the disease occurs in each sex, but is much more frequent in men than in women. It is a disease chiefly of the middle period of adult life, beginning commonly between the ages of thirty and forty-five; the first symptoms occurred in the man at forty-one, in the woman at thirty-two. The earliest case I have known commenced at nineteen, the latest at fifty-five. Neurotic heredity is rare; it is to be traced only in a tenth of the cases, and is absent in both the patients before you. In neither of them is there a history of syphilis, and in this respect also they illustrate the common rule. It is as rare to have a history of constitutional syphilis in the subjects of ataxic paraplegia as it is common to have such a history in the subjects of pure locomotor ataxy. Among exciting causes, exposure to cold can be traced in some as a probable influence. In one young lady the first symptoms succeeded a season of balls, at which, when heated, she was in the habit of cooling herself at open windows, and, on reaching home, would often throw herself on the bed and sleep through the night or the morning in clothes saturated with perspiration. Mental distress and anxiety, especially coupled with over-exertion, have been the apparent cause in some cases. This woman noticed the first symptoms after the death of her mistress, whom she had nursed through a long and anxious illness. Rarely, a severe concussion of the spine has occurred some months before the onset. A concussion may induce paraplegia by actual injury, probably by causing minute extravasations, from which secondary inflammation spreads. But such paraplegia comes on in a few weeks, whereas, in the cases we are considering, the symptoms succeeded the injury after a long interval and then developed very slowly. The same sequence is seen in other degenerations of the spine, and it therefore seems probable that a concussion may cause derangement of the process of nutrition of the nerve elements, the effects of which are manifested only after it has slowly attained a considerable degree. In many cases, as in this man, no cause can be traced. A cause there must be, but its nature is such as to elude our search.

The onset of the symptoms is always gradual, and the progress is commonly slow. Even when it is steadily progressive, at no time stationary, years may pass before the power of walking is lost. This man can still walk, although with difficulty, and it is now eleven years since he could last say that he was well. The woman's symptoms commenced [illegible] years ago, but it was only at Christmas last that she took to her bed. In very rare cases the onset has been less chronic, almost subacute, and the symptoms have attained a considerable degree of intensity in a few months. The first manifestation of the disease in almost all cases is in the legs, and the symptoms may remain limited to them throughout, or, as in these patients, may afterwards invade the arms in various degrees. The characteristic feature of the disease is a slow and simultaneous development of two symptoms — defect of power and defect of coördination, weakness and ataxy. The patient at first finds that he tires more readily than before; he is glad to ride distances which before it was a pleasure to him to walk. The clinical clerk who took this man's history has recognised the fact by noting as the earliest symptom "a tendency to frequent use of twopenny 'busses." As soon as the patient is conscious of weakness, he is conscious also of some unsteadiness. He notices it when he turns suddenly, when he walks in the dark or on an uneven pavement, or when, in order to wash his face, he shuts his eyes and bends forward. There are no pains in the legs. They may ache a little after walking, but there are scarcely ever the sharp pains which, as you know, are so common in tabes. There is sometimes a little dull pain in the back, and not unfrequently there is a good deal of aching pain in the sacral region, but that is all. The motor symptoms slowly increase. If you then see the patient, you will find distinct loss of power in the legs. You may, indeed, not discover it at first, for the patient as he sits may extend his legs with force; but if you carefully examine, as you should do, the power of each set of muscles, you will find that the flexors are distinctly weak, the flexors of the hip especially, the flexors of the knee in less degree. The fact of the defect is often, as it were, emphasised by being greater in one leg than in the other. But if you have often to search for the weakness, it is not so with the incoördination which usually obtrudes itself upon your notice. The patient's gait is distinctly unsteady; if he turns quickly he reels, and has to bring his foot suddenly to the ground to maintain his equilibrium and to save himself from falling. It may be impossible for him to stand with his feet together and eyes closed, and even with open eyes he oscillates, and the irregularity of the muscular contractions is shown, if the feet are bare, by the quick movement of the tendons on the dorsum of the foot. The incoördination may resemble perfectly that of many cases of tabes, although there is not the "high action" of the legs sometimes present in the latter disease. I have admitted this man into the hospital as an illustrative case, because he has been under my observation for many years, and I have been able to watch the slow course of his symptoms. It is now eight years since I first saw him, and at that time his gait was exactly like that of most tabetic patients. I remember often asking a student from what the man appeared to be suffering, and the answer always was "locomotor ataxy." This ataxy is not confined to locomotion. It is equally evident in the irregular movement of the leg, if, as the patient lies, he attempts to touch some object when his eyes are closed. If you should come to the conclusion that such a patient is suffering from locomotor ataxy, and proceed to confirm your diagnosis by testing the knee-jerk, you will discover at once the anomalous feature of the case. Instead of being lost, the knee-jerk is increased, and you are able without difficulty to obtain a foot clonus. Indeed, you can often obtain also a rectus clonus by suddenly depressing the patella, as the patient lies, and thus extending the rectus—always a proof of a great excess of the peculiar "myotatic" irritability on which these phenomena depend. You can obtain, as you see, both rectus and foot clonus in each of the patients before you. Thus, an increase of this irritability attends, in this disease, as it so often does, weakness of the legs, and it attends the weakness in spite of the existence of a symptom commonly associated with entire loss of these phenomena.

I had told you that lightning pains are absent. I have, indeed, met with them in one case, but they were transient and ceased after a few months, not again to return. Their absence in harmony with the absence of these pains is the general integrity of sensation, which is not impaired upon either of the limbs or trunk. Sometimes the patient complains of "numbness" or "tingling" in the

extremities, but there is no corresponding loss of sensation, or only a very slight and doubtful impairment of tactile sensibility on the fingers and toes, scarcely ever amounting to actual loss. Here, again, is another marked difference from tabes. Reflex action from the sole is also perfect and is commonly excessive. The arms are often free, but they sometimes present symptoms similar to those of the legs: incoördination of movement of the fingers, weakness, and increased myotatic irritability. Often, indeed, there is this increased irritability when the patient is conscious of no weakness, but you will then find, if you test power, that it is below the average. If the arms suffer, one is often affected in greater degree. In this woman there is very marked incoördination of movement of the right hand, and none of the left. In the man there is some incoördination of both hands. Sexual power is often lost early in the disease. The sphincters are frequently impaired, sometimes early, but the impairment rarely reaches a considerable degree. In the woman, when first admitted, there was well-marked reflex incontinence of urine. There was no persistent dribbling and no persistent distension of the bladder, but as soon as a certain quantity of urine had accumulated in it, the bladder was emptied involuntarily. The iris usually acts to light. It does so perfectly in each of the patients before you. I have seen loss of the light-reflex in two or three cases, and have once known accommodation to be lost, the action to light being normal. Optic nerve atrophy occurs only in very rare cases, less frequently than in tabes; I have seen one case in which there were indications of a retro-ocular axial neuritis. The external ocular muscles are usually normal, and there is no nystagmus. Slight impairment of articulation is not uncommon; sometimes there are irregular tremulous movements of the face resembling those of general paralysis, and this in cases in which there is no mental change. Westphal has observed marked ataxy of the facial muscles. As a rule the mental state is either normal or there is merely slight failure of memory. Undue frequency of the pulse is occasionally present, but is less common than in tabes.

As the disease increases the muscular power becomes more and more impaired, usually without much increase in the incoördination, which sinks into the background as the paralysis increases, and the patient has to have recourse to supports which at the same time afford him guidance. The increased myotatic irritability continues; stiffness and rigidity develop as its consequence. Thus the aspect of the patient comes to be that of spastic paraplegia, the feet drag as the patient walks, shake from clonus when he stops, and the legs are hauled forwards with visible effort at each step. Indications of unsteadiness may still be observed in isolated movements. This condition has been reached in each of these patients. In the woman the loss of power is so great that she can scarcely move her legs as she lies in bed; nevertheless, she can walk with assistance, because extensor spasm comes on and gives the legs the rigidity and firmness which the will cannot produce. The reflex mechanism on which this extensor spasm depends is probably that which is naturally involved in the act of standing, and it thus enables the patient to stand when voluntary power is insufficient for the purpose. But the unsteadiness still exists: if she closes her eyes she would fall at once were she not firmly held. In the man the palsy and rigidity have reached a much higher degree in the left leg than in the right. He can only walk with the help of crutches and by suspending the left foot in a sling from his shoulders, by the aid of which he can haul the leg forward, and then its rigidity enables it to bear some of the weight of the body; but if he shuts his eyes he falls at once. The spasm in the leg is very inconvenient to him, for it sometimes comes on while he is sitting, and the involuntary extension of the hip is so forcible that it is apt to make him slip off the chair on to the ground. In spite of the progress of the weakness, sensation usually continues normal: it is so in this woman; in the man there is the very trifling impairment of sensation I have just mentioned. There is no loss to pain or to temperature, and there is no absolute loss of tactile sensibility, but when he is touched on the toes he is not quite certain which toe is touched. The arms, if previously free, may suffer in the later stage of the disease, or they may remain throughout free from any symptoms of palsy or incoördination. Often, as in these two patients, there is slight ataxy in the arms, but no considerable impairment of power, even in the later stage of the disease. The reflex action of the pupils, unless early lost, continues [illegible]

out. The rule, no wasting of the muscles and no change in electrical excitability. The symptoms present, cases, variations from this type. Sensation in eyx, legs may be impaired and the knee-jerk may be lost. These cases are intermediate between the form now under consideration and pure tabes; they are, however, very rare, and do not constitute more than 5 per cent. of the cases in which ataxy and weakness come on together.

The disease has little tendency to cause death; indeed, the fatal cases have, for the most part, been untypical, and do not convey an accurate idea of the characters of the disease. The chief danger to life is from the accidents common to all chronic spinal affections, and especially from kidney disease secondary to retention. Among complications, the most important are mental changes resembling those of general paralysis of the insane, of which, indeed, this combined sclerosis may form part. Slight muscular atrophy sometimes occurs. Arthritis of doubtful significance has been once observed. A patient of Westphal's, who presented derangement of the sympathetic, died from peculiar spasm of the muscles of respiration. Visceral crises, however, are practically unknown.

What is the lesion that underlies these symptoms—this complex and progressive? Our knowledge of the pathological anatomy of the disease is meagre, being based on a few observations[1] on cases that have been, for the most part, more acute than the disease generally is, and in some other respects untypical. Of the lesion in the common form of the disease, the case of which is very chronic, we possess scarcely any accounts. This is sufficiently explained by the fact that the disease has so little tendency to cause death. "Nec silet mors," the apt motto of the Pathological Society, is true chiefly of disease that kills. But the facts of fatal cases are sufficient to show us clearly the general character of the lesion. In all cases the spinal cord has presented sclerosis of both posterior and lateral columns; but the precise extent and degree of the degeneration seem subject to considerable variations. As a general rule, the sclerosis of the posterior columns differs from that of tabes in two particulars. First, it is not more intense, and often is less intense, in the lumbar than in the dorsal region of the cord. Sometimes, indeed, in the middle and lower parts of the lumbar region the posterior columns may be free from sclerosis, although it is considerable in the dorsal region and at the junction of this with the lumbar enlargement. The second difference is that the sclerosis has rarely the special intensity in the root-zone of the postero-external column that characterises the lesion of tabes. The part of the external column near the commissure and near the neck of the posterior horn usually remains free everywhere. Sometimes the degeneration does not extend up to the posterior surface of the cord; it may affect chiefly the middle three-fifths of the posterior columns. When the degeneration is considerable, the posterior median columns in the upper part of the cord may present the usual ascending degeneration of secondary origin. When the lesion is slight in degree in the lower half of the cord, there may be only a slight diffuse degeneration of these columns in the cervical region, similar to that elsewhere, and not the more intense limited affection of the median part that occurs when there is a considerable lesion of the column lower down. The degeneration in the lateral columns is also variable in extent and position, and is not often "systemic" in character—at least, it does not correspond to a single system of fibres. In one or two cases, indeed, the whole pyramidal tract, and this alone, has been degenerated; but more often the sclerosis, while intense in the pyramidal tract, also extends in front of this into the mixed zone of the lateral columns. A similar extension, I may remind you, is met with in the sclerosis that attends degeneration of the anterior cornua. The "lateral limiting layer," between the pyramidal tract and the grey matter, may be also invaded. The direct cerebellar tract often escapes. But in some cases there is a zone of sclerosis round the periphery of the cord, involving the cerebellar tract where this exists, and extending deeply into the lateral column in the position of the pyramidal tract. The latter has been found diseased, in some degree, in all [illegible]; in several the extent of its degeneration has been greater in the lower part of the cord than in the upper, but

[1] By Prevost, Arch. de Physiologie, t. iv.; Pierret, ib.; Babesieu, Virchow's Archiv, Bd. lxxvi.; Kahler and Pick, Arch. f. Psychiatrie, Bd. viii.; and Westphal, ib., Bd. viii. and x.,—the last being the most important.

in some it has been but slightly damaged. [illegible]pposes other degenerative diseases of the cord, there may [illegible] of [illegible]ase of connective tissue in the unaffected columns [illegible]y be so intense at some spots as to constitute areas of distinct sclerosis. As a rule, no morbid change has been recognised in the grey matter or in the membranes. In one case only was there slight meningitis. Disease of the ascending root of the fifth was found in a case in which there were corresponding symptoms. The peripheral nerves seem not to have been examined in any case. It is not likely that they are diseased. The muscles have been found normal.

(To be concluded.)

Remarks
ON
TREPHINING FOR EVACUATION OF INTRA-CRANIAL ABSCESS OCCURRING IN CONNEXION WITH SUPPURATIONS IN THE EAR;

WITH [illegible]E CASES IN WHICH IT WAS PRACTISED.

By W. HULKE, F.R.C.S., F.R.S.,
SURGEON TO [illegible]IDDLESEX AND ROYAL LONDON OPHTHALMIC HOSPITALS.

THE subject to which I invite attention is the question of trephining in cases of intra-cranial abscess occurring in connexion with suppurations in the middle and internal ear. That these contribute a large proportion to the total number of intra-cranial abscesses from all causes, and that they nearly always end in death, are facts so familiar to [illegible] that it has seemed to me unnecessary to illustrate them by statistics. So far as I know, the only exception to the fatal termination is where a sufficiently free outlet has been formed by carious perforation or absorption permitting the escape of pus from the abscess into the external auditory meatus, or through the mastoid or squamosal, at the outer surface of the skull. Instances of such fortunate termination are so extremely infrequent, so absolutely exceptional, that their occurrence affords no excuse for inactivity, no encouragement to trust to an expectant treatment. The silence respecting trephining in such cases observed by the text-books in current use here, on the European continent, and in America, is probably referable in part to existing uncertainty of diagnosis, and in part to too high an estimate of the dangers incidental to the operation. It must be frankly avowed that whilst the pathological anatomist can demonstrate the several conditions known as *meningitis*, in its two forms limited and diffuse, *thrombosis* of the cerebral sinuses, and *abscess* in the cerebrum or cerebellum, the clinicist, notwithstanding the recent advance in cerebral physiology and pathology, cannot yet with like certainty distinguish between these disorders. Moreover, his difficulties are not infrequently increased by their concurrence, as when thrombosis of sinuses coexists with meningitis, and either or both of the foregoing with cerebral or cerebellar abscess; and the task of discrimination is occasionally rendered yet more difficult when the symptoms of the local are overlaid by those expressive of the general disorder summed up under pyæmia and septicæmia. However, the fact that the clinicist is not yet in the position to form a certain judgment concerning the precise nature of the local disorder in a given case does not, in presence of the almost certainly fatal termination of otitic intra-cranial abscess when left to take its natural course, exonerate him from further efforts; when his judgment attains to a high degree of probability, the propriety of a surgical operation for the evacuation of the abscess should be fairly faced. It is obvious that against diffuse meningitis, thrombosis of sinuses, and nearly as certainly where pyæmia or septicæmia is present, the resources of surgery cannot avail; and that operative measures can only hold out promise of relief in instances of localised suppuration—in abscess. An attempt to formulate schemata for the differential diagnosis of the several disorders just mentioned is beyond the scope of this communication, and I will now only say that the formation of abscess is usually more insidious and its course more chronic than that of diffuse inflammation. Two symptoms especially characteristic of otitic intra-cranial abscess are an abnormally slow pulse and low temperature. These have also been on several occasions noticed by me in intra-cranial abscesses of traumatic origin.

In discussing with others the question of trephining, it has been objected that the diagnosis is too uncertain to justify it; the risk of setting up septic inflammation, of doing irreparable mechanical injury to the brain, and of causing serious hæmorrhage in an inaccessible locality where bleeding vessels cannot be secured, are so great and so evident that trephining can only be expected to hasten the fatal end. Some risk must be encountered, but this is greatly reduced by the observance of strict antisepsis and by a cautious method of operating. The bloodvessels in the dura mater will generally avoid injury by the trephine when this is worked with a light hand; and as they are immediately apparent when the dura mater is uncovered, they can be avoided when this membrane is incised, or, if cut, easily secured. Vessels more deeply placed, in pia mater or in brain, will also be usually pressed aside and remain unwounded where these latter parts are pierced with a trocar or a blunt-ended director—an instrument to be preferred to the aspirator, unless this is worked with a very slight degree of exhaustion. A high degree of exhaustion is unnecessary, for the pus within the skull stands under a much greater pressure than might be supposed; and it may even be injurious, since the consistence of the brain tissue allows it to be sucked through a tube of even moderate calibre; moreover, rapid and complete evacuation of an abscess may induce hæmorrhage. In the first of the following cases, where the lower part of the temporo-sphenoidal lobe, and in the second, where the cerebellum was deeply punctured, the tracks of the instrument were marked by only a little blood, and they were free from all signs of inflammation.

The presence of an intra-cranial abscess being suspected, the question of its situation next follows. Is it above or below the tentorium, in the temporo-sphenoidal lobe, or in the cerebellum? The want of leisure and opportunity have prevented me from testing by the statistics of recorded cases the relative frequency of the occurrence of abscess in these situations, and whether this is influenced by age. The impression left on my mind by the recollection of several dissections is that in the young abscess in the temporo-sphenoidal lobe is more frequent, whereas in adults the opposite occurs. Where hemiplegia or hemispasm are present, the presumption is in favour of the abscess being above rather than below the plane of the tentorium. Pain, and even tenderness, are of less value as localising symptoms. They may even lead to a mistake in diagnosis, as in the first of the following cases, where the pain was referred to a very tender spot above the ear, whilst the abscess was situated in the cerebellum; and in the second case, where pain was felt acutely in the occiput and the nape, whilst the abscess was in the temporo-sphenoidal lobe, over the tegmen tympani.

CASE 1. *Chronic Otorrhœa; Caries of the Petrosal; Abscess in the Cerebellum, erroneously supposed to be in the Temporo-sphenoidal Lobe; Puncture of the Lobe.*—B. A——, aged forty-five, a tall well-grown man, of good muscular development, a baker, was admitted into the Middlesex Hospital on Oct. 30th, 1885, under the care of Dr. Cayley. He complained of severe pain in the left half of his head, most intense in the occiput, radiating over the temporal and frontal regions. Immediately above the pinna of the left ear was a spot extremely tender on pressure. He said that firm pressure here caused increased pain in the head, which continued for two hours or more. There was also distinct but less acute tenderness above and behind the mastoid process. A fetid, fusiform discharge oozed from the left auditory meatus. The ticking of a watch, in contact, was inaudible by this ear. His face seemed to be slightly drawn towards the right, and the furrows in the left appeared less deep than those in the right side of the face. A slight deviation of the tongue towards the left was thought to be present, but respecting this there was some doubt. He could not [illegible] the left eyelid as tightly as the right. Mastication caused so much pain, referred to the temporo-maxillary joint, that for the last three weeks he had been obliged to abstain from solid food. Otorrhœa was present also on the right side; the hearing of this ear was impaired, but it still perceived the tick [illegible] watch.

History.—The patient said he had had a p[urulent] discharge from both ears since childhood, oozing consta[ntly] from the right and occasionally from the left ear. [She] had had scarlatina in childhood, but he did not know whether the affection of the ears followed or preceded this. Twenty years ago he had a polypus extracted from the left ear, and another was removed from it six years later. About three weeks previously he began to have severe aching in the left ear, and a few days later pain in the back of the head. This at first was accompanied by vomiting, which continued two days. The earache and headache were extremely severe, and at night so intense as to prevent sleep. The otorrhœa continued during this time, and it was sometimes tinged with blood.

From the time of the patient's admission into the hospital his condition continued to grow worse. His temperature on only one day touched 100° F. On Nov. 5th and 6th it was 97·6° and 97·2°; the pulse on these days being 52 and 54. On Nov. 7th, when I saw him in consultation with Dr. Cayley, he was unconscious to external impressions, but restless, often lifting his left hand to the same side of his head, as if he felt pain there. He swallowed with difficulty, and had lost control over his sphincters. Intra-cranial abscess was diagnosed; and in the absence of other localising symptoms the extreme tenderness *above* the ear was taken as an indication that the abscess was probably above the level of the attachment of the tentorium in the middle fossa. The squamosal was therefore perforated with a small trephine, the pin of which was set at the distance of one centimetre above the external auditory meatus. The dura mater was divided, and a blunt-ended director was passed through the opening towards the tegmen tympani until its end impinged upon the upper surface of the petrosal. No pus escaped. It was evident that the operation had failed of its purpose. The coma deepened. At 10 P.M. his lips were blue; his breathing slightly stertorous, with tracheal râles; pulse 140. Death occurred at 2.15 P.M next day.

The following extracts are taken from the record of the post-mortem examination made by Dr. Fowler: "There was a little hæmorrhage at the parts around the wound, but no inflammatory changes.....In the left cerebellar hemisphere, about the centre of its anterior border, where this is in contact with the petrous part of the temporal bone, there was an abscess the size of a walnut, containing thick greenish-yellow pus. This was in contact with a small aperture in the dura mater through which pus had burrowed from a carious portion of the temporal bone in connexion with disease of the internal ear. The walls of the abscess were almost smooth and fairly well defined. The left cerebellar hemisphere was considerably swollen, and it had evidently compressed the pons and medulla. There were no other marked changes in the brain."

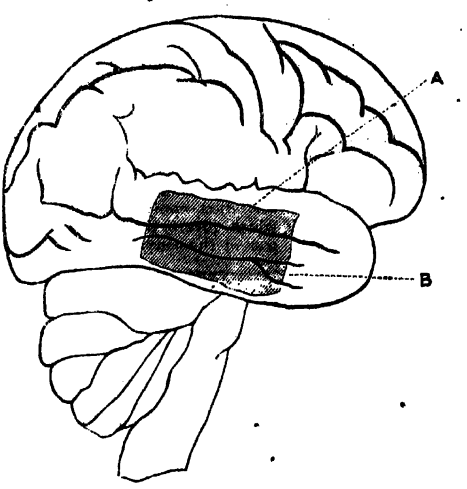
The post-mortem inspection left no doubt in my mind that this abscess could have been tapped by trephining the occipital bone below the level of the attachment of the tentorium; so it has ever since been to me a subject of regret that this was not done immediately upon the failure of the puncture of the temporo-sphenoidal lobe. Whilst it failed to accomplish the purpose for which it was undertaken, the operation was not wholly without value, tending, as it did, to show its relatively slight dangers.

CASE 2. *Chronic Otorrhœa: Polypus: Carious Perforation of the Tegmen Tympani, and Abscess in the Temporo-sphenoidal Lobe.* R. M——, aged nineteen, a maid-of-all-work, was admitted into the Middlesex Hospital, under Dr. Cayley, on March 24th last.

Present state.—A well-grown brunette. She has a dull apathetic expression, and complains of headache, most intense at the vertex and in the right side of the head. Her right ear is absolutely deaf. The orifice of the meatus externus is full of fetid pus, on removing which a polypus is apparent. At the bottom of the meatus bare bone is felt with a probe. There is great tenderness over the mastoid process, and in a less degree over other parts of the right side of the head. The right side of the face appears slightly wanting in expression. Temperature in the right axilla, 98°; in the left, 97·8°. Pulse 50, small, and slightly irregular. Her left ear is also very deaf.

History.—Her mother states that four years ago she attended the Throat and Ear Hospital in Golden-square for a discharge from both ears. These were syringed and [her] tonsils cut out. Four weeks ago she fell, striking the back of her head against a table. Her scalp was not hurt, but she [was] stupefied and stupid for a day or two after. During the next three weeks she had complained on and off of headache, and she had occasionally vomited. On March 16th, one week prior to her admission into the hospital, the headache became more intense, and she vomited more frequently, and the urgency of these symptoms continuing to increase, she was brought to the hospital.

At a consultation with Dr. Cayley on March 24th, the history and symptoms were considered to indicate with much probability an intra-cranial abscess, and the question of trephining was discussed. The extreme tenderness of the mastoid process, and the known fact that pus pent up in the antrum mastoideum does occasionally give rise to symptoms closely simulating those of intra-cranial abscess suggested the propriety of first exploring this process. Bearing in mind the great variation in the course of the lateral sinus, its occasional advance in front of its usual position, and its approach sometimes towards the outer shell of the process, which is exceptionally found defective over it, the perforation was made with a small gouge, in preference to the drill recommended by some authors. After chipping away the outer shell at a small circular spot limited in front by the posterior margin of the auditory meatus and above by the "supra-mastoid ridge," diploëtic tissue was exposed; it appeared healthy. The antrum mastoideum not coming into view, the excavation was cautiously continued until exposure of the dura mater forming the ov[erhang] of the lateral sinus barred further advance. It was [thus] demonstrated that the symptoms were not due to ma[stoid] suppuration.



Two days later (March 26th), her condition having become more grave, it was decided to trephine the skull in search of abscess. Influenced by the history of a fall on the occiput, and by the recollection of the position of the abscess in the preceding case, in the absence of definite localising symptoms we decided to explore for abscess in the cerebellum. The spot chosen for perforating the occipital bone was situated about two centimetres behind and inwards from the mastoid process, the crown of the trephine encroaching on the inferior curved line. This spot was selected as being sufficiently beneath the lowest level of the horizontal part of the lateral sinus, and also sufficiently removed inwards from the descending part of the sinus. The dependent position of the spot was also thought advantageous for the drainage of the abscess, if found. The spot was easily uncovered by raising the scalp by a horseshoe incision, the ends of which lay slightly above the level of the external occipital tuberosity, and the bend slightly below the level of a line joining the apices of the mastoid processes. The muscles were divided by a cut down to the bone parallel to the "superior curved line," and, together with the periosteum, peeled down to a sufficient extent with a raspatory. The "inferior curved line," easily felt, proved a good guide to the selected spot. The severed occipital artery was easily secured with a pressure-forceps and afterwards tied. The bone, in this girl extremely thin, was easily perforated with a gouge. On dividing the dura mater a small quantity of colourless limpid cerebro-spinal fluid welled out. A grooved blunt director was then passed through the opening in the direction of the internal auditory meatus until it touched the posterior surface of the petrosal, and no pus escaping, the director was passed twice again in directions approximately parallel to the surface of the petrosal at slightly increasing distances from this. I was induced to do this by the recollection that in some instances a small band of seemingly unchanged cerebellar tissue has been found between the abscess and the petrosal. It was too evident that the exploration had failed. The flap was laid down, and the wound closed, provision being made for drainage. It was particularly noticed that no change in the pulse or respiration occurred during the operation.

March 27th: Temperature 97·2°; pulse 54. She vomited frequently in the course of the evening, and was in a drowsy condition through the night, but not asleep. She still complained of severe headache, but did not refer it particularly to any one part of the head. At 8 P.M., temperature 97·4°; pulse 58.—28th: At 10 P.M., temperature 97·4°; pulse 56. She passed the night without vomiting, and is now asking for food. She seems very drowsy, and says that her head is not so painful. Evening temperature 97·2°; pulse 54.—29th: At 10 A.M., temperature 97·2°; pulse 56. Vomited once yesterday. Passed a quiet night, and is now sleeping. At 8 P.M., temperature 97·4°; pulse [illegible].—31st: At 10 A.M., temperature 97·4°; pulse 56; respirati[on] 16.

Passed a quiet night, sleeping. At 8 P.M. temperature 98·4°; pulse 52.

April 1st.—At 10 A.M., temperature 99·4°, [illegible] small, irregular, and respiration 19. During the greater [illegible] the last twenty-four hours she has been lying as if asleep, and now no longer answers when questioned. The right pupil is dilated and the left contracted. When the arms, usually semi-flexed, are laid in full extension, she moves the right arm better than the left, which latter is distinctly weaker. The eyelids twitch when the eyelashes or cheek are touched. Epigastric, abdominal, and plantar reflexes normal. No ankle clonus. During this examination the face became flushed and the breathing slightly stertorous. The left forearm was convulsively pronated, and both hands and the feet were spastically flexed. This attack quickly passed off, but was repeated four times in the course of the next hour, and whilst the wounds were being dressed. The ear still discharged fetid pus. The mastoid and occipital wounds are free from inflammatory swelling; about an ounce of laudable pus has escaped from the occipital drainage-tube. At the midday visit it was noticed that, whereas she moved spontaneously the right arm and withdrew it when it was slightly pinched, she moved the left arm only when firmly pinched, and this movement was feebly executed; paresis of this arm was present. She does not notice, even when very loudly addressed. Reluctant to abandon her without a further attempt for her relief, at 5.30 P.M. the squamosal was trephined above the external auditory meatus, the dura mater divided, and a grooved director passed in the direction of the tegmen tympani; about half an ounce of thick, fetid, dark greenish-yellow pus escaped. The opening in the dura mater was enlarged sufficiently to permit the insertion of a drainage-tube, and the wound was dressed. Owing to the greater thickness of the bone at the lower part of the circle, a thin scale of the inner table escaped division by the trephine and remained when the disc was lifted out. This was left *in situ*, as there seemed sufficient space for the drainage-tube above it, and because it was bordered by a branch of the middle meningeal artery, the division of which, not appearing necessary for the operation, was to be avoided. Shortly after the operation, when the patient had been returned to bed, the pulse was found to have risen to 100, and an hour later it had reached 128. At 7 P.M., temperature 100·2°; at 8.30 P.M., temperature 124°, respiration 22; restless, insensible; pupils dilated, equal; slight and very transient convulsions affecting the whole body. Death occurred at 5 A.M. on the 2nd.

The following extracts are from the record of the post-mortem examination, made twelve hours after death, on April 2nd, by Dr. Fowler: "Cerebral convolutions extremely flattened, and sulci effused. Flattening almost equal, and not more marked on the right than on the left side of the brain.....No evidence of meningitis except about the centre of the right middle temporo-sphenoidal convolutions, where over an area apparently about the size of a shilling the brain was adherent to the parietal layer of the arachnoid. This lobe (right temporo-sphenoidal) was very soft, and, in attempting to remove it, it broke down and some pus escaped. The left half of the brain was then removed, and subsequently the right half and the membranes. The upper surface of the right petrous bone close to the juncture with the squamous showed several areas where perforation had occurred, and where the pus was evidently present in the bone beneath and was welling through the perforations. There was another perforation at the junction of the squamosal and petrous bone in the posterior fossa of the skull where the lateral sinus grooves this latter. This had caused thrombosis of the sinus and complete obstruction of its lumen for a distance of nearly an inch. In the operation on the mastoid cells the inner table had been perforated exactly at the spot where it is covered by the lateral sinus, but the sinus had not been opened. The opening into the cerebellum was seen about the centre of the right lower fossa of the occipital bone, nearly equal to the calibre of a quill pen. The dura mater had been perforated through a smaller opening, and the cerebellum pierced in a forward direction. There was no sign of inflammation in the neighbourhood of the cerebellar wound, nor was there any abscess in the cerebellum. After hardening in spirit of wine the abscess in the temporo-sphenoidal lobe was opened, and found to be a well-defined cavity, the size of a walnut. It contained some creamy greenish-yellow pus, which had a fetid odour. This cavity had been punctured in the operation, but owing to the rent made in the brain substance in removing the brain from the skull, and also to the drainage-tube having been removed, the exact line of the puncture could not be seen. The trephine wound in the skull was incomplete, both tables having been removed in the upper half of the area,

Schema of situation and magnitude of abscess.
A, Half an inch from fissure. B, One inch and a half from tip of temporo-sphenoidal lobe. Roughly, two inches square. "It measured about two inches square, and extended to within an inch and a half of the tip of the temporo-sphenoidal lobe, and half an inch from the Sylvian fissure."

whilst over the lower half only the outer table had been taken away. The incision in the dura mater was much smaller than the opening in the bone, and across the part of the membrane exposed a vessel ran obliquely.

CASE 3. *Chronic Otorrhœa; Abscess in Cerebellum, evacuated by Trephining the Occipital Bone.*—On April 14th last I saw in consultation with Mr. J. A. Bloxam, and her medical attendants, Messrs. Montgomery and Plumbe, a lady, aged about fifty-five years, who had long been the subject of a purulent discharge from the right ear. She was comatose, her cheeks and lips were bluish, and she breathed heavily, but without stertor. She occasionally lifted her left hand to her mouth and left cheek and held it there; this was said to be an old habit. The mouth appeared to be slightly drawn to the left; this also had been observed long prior to the present illness. Shortly before we saw her she had tried to leave her bed, moving both legs. Pulse slow and temperature low.

Dr. Montgomery informed us that the present illness dated from a journey to London, sixteen days previously. On her return home she complained of aching in the right ear and right side of the head, with stiffness and uneasiness in the nape. These symptoms continued without notable variation until three or four days before we saw her, when a slight drowsiness was noticed, and she was advised to stay in bed, which she did reluctantly. The day before we met the drowsiness was less, and she wished to get up. On the morning of our consultation the drowsiness had again increased; it continued to deepen throughout the day, and had taken the form of coma before we saw her at 5.30 P.M. She had for many years had otorrhœa, and the ear had long been absolutely deaf.

It appeared to me that the history and present symptoms indicated abscess in the cerebellum—the depth of the coma, unattended with any evidence of left hemiplegia, was unfavourable to the supposition of abscess in the temporo-sphenoidal lobe,—and that in the presence of this its evacuation by trephining the occipital bone offered the only prospect, slender as it was, of saving life. This view was also that taken by Mr. Bloxam and the patient's medical attendants. It is unnecessary to detail the steps of the operation, as they differed in no essential from those practised in Case 2, except that the bone, unusually thick, was perforated with a trephine. The immediate effects of opening the abscess were striking. The pulse, when noted a few minutes after, was 72. The breathing, previously heavy,

had become easy; the cyanosis of the face disappeared; the coma was less deep. The patient moved, and, when disturbed by some mucus in the throat, rose on her elbows and made efforts to expel it. Dr. Montgomery wrote me that consciousness did not return, and that death took place in the following forenoon.

A desire not to prejudice judgment has led me to present these cases, without gloss, almost entirely in the original words in which they are recorded in my case-books. If it be objected that, as they were all three fatal, they fail to justify the treatment a trial of which I advocate, I may fairly rejoin that this simply shows the powerlessness of trephining to relieve at the very late stage at which it was practised. In the future we must strive at perfecting the early diagnosis of abscess, and this once made, we must boldly and without hesitation apply the same general principles of surgery which govern the treatment of abscess in any less noble part of the body.

OLIVER WENDELL HOLMES.

BY SAMUEL WILKS, M.D., F.R.S.

THE literary fame of Oliver Wendell Holmes is too well established to require any enforcement on the occasion of his visit to this country, but his connexion with the medical profession gives especial interest and zest to his writings for those who are of a like calling with himself. In this respect our author takes an almost unique position, for although it is true that literature has numbered amongst its devotees men who had been students of medicine, yet in most cases one profession has been discarded for the other, as in the examples of Smollett, Goldsmith, Keats, and others, where the doctor's craft was scarcely seen to gild their writings. With Wendell Holmes it is very different, for although he had long retired from the active pursuits of his profession he had retained until lately the professorial chair, and therefore ever had before him whatever the anatomy and physiology of the human body could teach, and their lessons are evident in every page of his writings. It is from this point of view I venture to give a few extracts from his works which come ready to hand as samples of his method. When it is remembered how intimately associated is the material structure of our frames with all those characteristics of men and women which we call mental, moral, or religious, it is obvious how much deeper and clearer must be the insight into human nature by one who has a profound knowledge of the sources from which many of them spring. How intimately states of health, forms of disease, or inherited temperaments affect the mental and moral qualities every medical man knows, but how often do we see them entirely overlooked or ignored by those who are regarded as our leading novelists or poets. At least this was so with many writers of the last generation, where the material basis and all the coarser functions of the body were hidden to give place to the more refined and elevated passions of the mind. A severance of this kind of natural phenomena has led to a reaction in the production of the realistic school, and we see the result in much of our modern literature, painting, and the drama. It has already reached its climax in certain French and English novels, in which the loathsomeness of the descriptions is usually sufficient to cause the reader to close their pages. Some of those who have protested against the modern realistic school have very unfairly dragged some of our profession into the mire, and have associated distinguished scientific men, whom they have been good enough to style materialists and vivisectionists, with those who can depict the horrible details of a murder on an immense canvas in the *salon*, or describe minutely the filthy particulars of the animal functions in a French novel. Wendell Holmes is a living protest against so gross a charge. These critics fall into the error of confounding the act of dissection with its exposure to the public eye. It need not here be said that those who wish to learn the intimate structure of the human body must remove the outer skin to enable them to discover the mechanism within, but the sight is not a pleasant one to the uninitiated eye, and the investigation is considerately kept from the public gaze. In a similar way, in order to obtain a perfect knowledge of all that pertains to the faculties, feelings, desires, and passions of the human being, the nature of men and women must be dissected and unravelled, so that those who have discovered the intimate connexion between the influences of a material kind and such passions as love and hatred are in the best position to portray human nature in all its attitudes. It by no means, however, follows that Zola need describe with the most minute details all the lower animal functions which the instincts command us to keep secret. Let him make the analysis if he pleases, and even use it in furtherance of his object, but he need not expose the details to public view. Balzac had no need to do this, and yet no writer shows a deeper insight into character as expressed in the ever-varying form and features.

Wendell Holmes has such a knowledge of the human frame as none but a good anatomist, physiologist, and pathologist could possess. His knowledge is apparent in every page of his writings, and gives to them their special value; yet a true artist's aim can be accomplished, and he no more ruffles the sensibilities than does Dickens in describing the very scum of our streets. In his last novel, "Mortal Antipathy," it is evident that he is cognisant, and has indeed a very large experience, of those animal and sexual instincts which go to make or mar much human happiness. That his mind is quite alive to the subject we see in his "Life of Emerson," where he says, "When Zola and his tribe cross the borders of science into its infected districts, leaving behind them the reserve and delicacy which the genuine scientific observer never forgets to carry with him, they disgust even those to whom the worst scenes they describe are too familiar. The true realist is such a man as Parent du Chatelet, exploring all that most tries the senses and the sentiments, and reporting all truthfully, but soberly and chastely, without needless circumstance or picturesque embellishment, for a useful end, and not for a mere sensational effect." Although on the authority of our hero the dissection need not be exposed to public gaze, it does enable the investigator to understand more thoroughly the beings with which he is dealing, and to see how all mankind are one, and how "one touch of nature makes the whole world kin." With Wendell Holmes this has produced a sympathy with his fellow-creatures which is one of the most characteristic features in his writings. "I do not know," he says, "what special gifts have been granted or denied me, but this I know, that I am like so many other of my fellow-creatures that when I smile I feel as if they must; when I cry, I think their eyes fill; and it always seems to me that when I am most truly myself I come nearest to them, and am sure of being listened to by the brothers and sisters of the larger family into which I was born so long ago. I have often feared they might be tired of me and what I tell them. But then, perhaps, would come a letter from some quiet body in some out-of-the-way place which showed me that I had said something which another had often felt but never said; or told the secret of another's heart in unburdening my own." In another place he says: "A writer is like a lover; and a talk with the right listener is so like an arm-and-arm walk in the moonlight, with the soft heart-beat just felt through the folds of muslin and broadcloth. I have no doubt each one of us has somewhere our own facsimile, so like in all things except the accidents of condition, that we should love each other like a pair of twins if our nature could once fairly meet. I know I have my counterpart in some state of this Union. I feel sure that there is an Englishman somewhere precisely like myself (I hope he does not drop his H's)." In "The Poet," also, he says: "Self-revelation from unknown and sometimes nameless friends, who write from strange corners, where the winds have wafted some stray words of theirs, which have lighted in the minds and reached the hearts of those to whom they were as the angel that stirred Bethesda. This is the best reward of authorship; it may not imply much talent and literary excellence, but it means that your way of thinking and feeling is just what some of your fellow-creatures needed."

His general scientific culture, enabling him to take into his regard the whole organic world, gives a much wider range to his vision, so that he has a truer grasp of human character than most writers. It is for this special reason I have taken up my pen, for it has not been sufficiently appreciated by most of his literary critics. In an early page of "The Autocrat" he describes how he had seen singers and pianoforte players making such strange motions that he laughed at them, and asked himself where they picked up these fine ecstatic airs; but when he went home he found

his canary bird piping its little tunes and [illegible]posing and waving about with all the droopings and li[illegible] languishing side-turning of head that he had b[illegible] at. He then asked himself who taught all this, [illegible] that he had erred in passing a judgment upon a creatu[illegible]ade of finer clay than himself. Wendell Holmes sees that all nature is one, and the same laws are operating through not only the animal but the vegetable world. The following passage I have more than once read to mothers who had not perceived that a time comes when their daughters are pining to leave the nest: "You may know that from the earlier stages of development of almost any vegetable you only want air, water, light, and warmth. But by and by, if it is to have special complex principles as a part of its organisation, they must be supplied by the soil: your peas will crack if the root of the tree gets no iron; your asparagus bed wants salt as much as you do. Just at the period of adolescence the mind often suddenly begins to come into flower and to set its fruit. Then it is that many young natures, having exhausted the spiritual soil around them of all it contains of the elements they demand, wither away undeveloped and uncoloured unless they are transplanted." In another place he says men often remind him of pears coming to maturity: "Some are ripe at twenty, like h[illegible]an jargonelles, and must be made the most of, for their [illegible]is soon over; some come into their perfect condition [illegible]e, like the autumn kinds, and they last better than t[illegible]mer fruit; and some, like the winter Nelis, have been cold and uninviting until all the rest have had their seasons, yet their glow and perfume last long after the frost and snow have done their worst with the orchards." The subject of evolution is before him when he describes an old black woman, "bent up, wrinkled, yellow-eyed, with long upper lip, projecting jaws, retreating chin, still, meek features, long arms, large flat hands, with uncoloured palms and slightly webbed fingers; it was impossible not to see in this old creature a hint of the gradation by which life climbs up through the lower natures to the highest human developments." In "The Poet" he says: "The scientific study of man is the most difficult of all branches of knowledge. It requires in the first place an entirely new terminology, to get rid of that monstrous load of prejudices with which every term applied to the malformation, the functional disturbances, and the organic diseases of the moral nature is at present burdened. Take that one word 'sin,' for instance: all those who have studied the subject from nature and not from books, know perfectly well that a certain fraction of what is so called is nothing more or less than a symptom of hysteria; that another fraction is the index of a limited degree of insanity; that still another is the result of a congenital tendency which removes the act we sit in judgment upon from the sphere of self-determination, if not entirely, at least to such an extent that the subject of the tendency cannot be judged by any normal standard." In another place he says: "You must have comparative theology as well as comparative anatomy. What would you make of a cat's little good-for-nothing collar-bone if you did not know that the same bone means a good deal in other creatures. You cannot know too much of your race and its beliefs, if you want to know anything about your Maker. I never found but one sect large enough to hold the whole of me." "And may I ask what that was?" "The human sect, including cannibals and all." Running through all his writings is the horror expressed at the idea of responsibility being attached to us for the sins of our forefathers. "Elsie Venner" was written with a theological moral to show his disbelief in a new-born infant being responsible for other people's acts, and suggests that Æsop's fable of the "Wolf and the Lamb" may have been written to denounce such a doctrine. Speaking of his heroine in the "Guardian Angel," he says: "The instincts and qualities belonging to the ancestral traits which predominated in the conflicts of mingled lives lay in the child in embryo waiting to come to maturity. It was as when several grafts bearing fruit that ripens at different times are growing upon the same stock. Her earlier impulses may have been derived directly from her father and mother, but all the ancestors who have been mentioned, and more or less obscurely many others, came uppermost in their time before the absolute and total result of their several forces had found its equilibrium in the character by which she was to be known as an individual. These inherited impulses were therefore many, conflicting, some of them dangerous; the World, the Flesh, and the Devil had mortgages on her life before its deed was put into her hands." In the same train of thought, he says: "So much are our minds alike, and yet you and I think we are peculiar, and that Nature broke her jelly-mould after shaping our cerebral convolutions."

Not only does Wendell Holmes make use of his professional knowledge in the portrayal of character, but he prominently brings forward the medical man in his various writings as one of the most important elements in the social community. He makes him honest, kind-hearted, and possessed of more than ordinary worldly wisdom. The following is from "Elsie Venner": "I have heard it said that the art of healing makes men hard-hearted and indifferent to human suffering. I am willing to own that there is often a professional hardness in surgeons, just as there is in theologians, only much less in degree than in these last. While I am writing this paragraph there passes by my window on his daily errand of duty, not seeing me, though I catch a glimpse of his manly features through the oval glass of his chaise as he rides by, a surgeon of skill and standing, so friendly, so modest, so tender-hearted in all his ways, that if he had not approved himself at once adroit and firm, one would have said that he was of too kindly a mould to be the minister of pain, even if it were saving pain. You may be sure that some men, even amongst those who have chosen the task of pruning their fellow-creatures, grow more and more thoughtful and truly compassionate in the midst of their cruel experience. They become less nervous, but more sympathetic. They have a truer sensibility for others' pain, the more they study pain and disease by the light of science." His remarks about medical men are always to the point. He says: "If you are to make choice of a physician, be sure you get one, if possible, with a cheerful and serene countenance. A physician is not, at least ought not to be, an executioner; and a sentence of death on his face is as bad as a warrant of execution signed by the governor. As a general rule, no man has a right to tell another by word or look that he is going to die. If you will only let nature and the God of nature alone, persons will commonly learn their condition as early as they ought to know it, and not to be cheated out of their natural birthright of hope and recovery." This advice by no means prevents his perceiving the moment when the doctor's presence may give place to that of others, for he says: "Do not overlook the desire for spiritual advice and consolation which patients sometimes feel, for as part of medical treatment it is the physician's business to detect the hidden longing for the food of the soul as much as for any form of bodily nourishment." In speaking of the different features of persons, he says: "It is the same thing with a patient: his disease has features of its own; there never was, and never will be, another case in all respects exactly like it. If a doctor has science without common sense, he treats a fever, but not this man's fever; if he has common sense without science, he treats this man's fever without knowing the general laws that govern all fevers and all vital movements. The men who have science only begin too far back, and before they get as far as the case in hand the patient has very likely gone to visit his deceased relatives." In one of his novels he describes the doctor as "sixty-three years old, a bald crown, as every doctor should have; a consulting practitioner's mouth—that is, movable round the corners while the case is under examination, but both corners well drawn down and kept so when the final opinion is made up. ..... Some very silly people thought the old doctor did not believe in medicine because he gave less than certain poor half-taught creatures in the smaller neighbouring towns, who took advantage of people's sickness to disgust and disturb them with all manner of ill-smelling and ill-behaving drugs. To tell the truth, he hated to give anything noxious or loathsome to those who were uncomfortable enough already, unless he was very sure it would do good; in which case he never played with drugs, but gave good, honest, efficient doses." His medical or physiological knowledge is constantly cropping up in his descriptions of persons and their doings: "Ah! it is the pale passions which are the fiercest; it is the violence of the chill that gives the measure of the fever. The fighting boy of our school always turned white when he went out to a pitched battle with the bully of some neighbouring village; but we know what his bloodless cheeks meant: the blood was all in his stout heart; he was a slight boy, and there was not enough to redden his face and fill his heart both at once." A poor fellow who is ill and full of pain is not in a con-

dition to judge fairly, and his friends cannot accept his verdict: "Many an honest ignorant man has given us pathology when he thought he was giving us psychology. It is a remark which I have heard from the wise patriarch of the medical profession among us, that the moral condition of patients with disease *above* the great breathing muscle—the diaphragm—is much more hopeful than that of patients with disease *below* it—in the digestive organs." In speaking of poor little children, who are often made the subjects of persecution by well-meaning religious people, Holmes says of one of them who had escaped: "The child would have died, no doubt; and if properly managed, might have added another to the long catalogue of wasting children who have been so cruelly played upon by spiritual physiologists, often with the best intentions, as ever the subjects of a rare disease by the curious students of science. ..... I have no doubt that disgust is implanted in the minds of many healthy children by early surfeits of pathological piety. I do verily believe that He who took children in His arms and blessed them, loved the healthiest and most playful of them just as well as those who were richest in the tuberculous virtues." He uses similar medical expressions in speaking of a girl who was in a prolonged hysterical state: "The poor little soul had been in one of those trances that belong to the spiritual pathology of higher natures, mostly those of women." That he knows, however, what hysteria is the following will prove: "The young girl looks innocent enough; but what does a blush prove, and what does its absence prove, on one of those innocent faces? There is nothing in all this world that can lie and cheat like the face and the tongue of a young girl. Just give her a little touch of hysteria—I don't mean enough of it to make her friends call the doctor in, but a slight hint of it in the nervous system,—and Machiavelli might take lessons of her."

The study of women in all their nervous vagaries has been a favourite one with Holmes, and he has a humorous and telling way of exemplifying great truths as few other writers have. Everyone knows how in emotional conditions laughing and crying are associated, or that allied movements of the chest are the manifestations of both of them. Holmes puts it thus: "Laughter and tears are meant to turn the wheels of the same machinery of sensibility—one is wind power and the other water power, that is all." He is very fond of likening the human form to a machine, thus: "Our brains are seventy-year clocks. The Angel of Life winds them up once for all, then closes the case and gives the key into the hand of the Angel of the Resurrection. Tic-tac! tic-tac! go the wheels of thought; our will cannot stop them; they cannot stop themselves; sleep cannot still them; madness only makes them go faster; death alone can break into the case, and, seizing the even-swinging pendulum which we call the heart, silence at last the clicking of the terrible escapement we have carried so long beneath our wrinkled foreheads."

> "Then mark the cloven sphere that holds
> All thought in its mysterious folds,
> That feels sensation's faintest thrill,
> And flashes forth the sovereign will;
> Think on the stormy world that dwells,
> Locked in its dim and clustering cells,
> The lightning gleams of power it sheds
> Along its hollow glassy threads."

The expressions gained from medicine are often very applicable and amusing. Holmes says when he was young he always avoided a story with a moral, and yet in his later years he had written a couple of "medicated novels": "Now take a poet like Cowper; he had a mental neuralgia a great deal worse in many respects than tic douloureux, confined to the face.....Many women die worried out of life by the perpetual teasing of an inflamed neuralgic conscience." At an entertainment he speaks of the first laugh which "broke out as premature; it was a sporadic laugh, and did not become epidemic." He is too polite and too loyal to the profession to make a coarse joke at its expense, but in speaking of a lady in one of his works he says, "Her daughter had also married well, to a member of what we may call the post-medical profession—that, namely, which deals with the mortal frame after the practitioners of the healing art have done with it and taken their leave." His allusions are often like this, merely suggestive, but consequently the more humorous, as when speaking of the old hall "with the sculptured unpunishable cherubs over its portal." Wendell Holmes has written very little which can be called purely medical. Some years ago he contributed to journals papers on puerperal fever and on the microscope. He believe, the term *cutis ænea* for Addison's disease. Other writings were of a literary kind, but many [illegible] by, if not founded on, his physiological reflections as, for example, a very interesting article on the "Physiology of Versification and the Harmonies of Organic and Animal Life," showing how rhythm, metre, accent, &c., depend on respiration and the circulation.

As the subject of wine-drinking is always under discussion, we will hear what our author says in its favour in one respect—that is, its use at dinner in equalising divergent tempers and rubbing off asperities: "Whatever may be the hygienic advantages or disadvantages of wine, I, for one, except for particular ends, believe in water, and, I blush to say it, in black tea; there is no doubt about its being the grand specific against dull dinners. A score of people come together in all moods of mind and body. The problem is, in the space of one hour, more or less, to bring them all into the same condition of slightly exalted life. Food alone is enough for one person, perhaps talk alone for another; but the grand equaliser and fraterniser which works up the radiators to their maximum radiation, and the absorbents to their maximum receptivity, is now just where it was when six great vessels containing water were changed into the best of wine."

Wendell Holmes has been called poet, litterateur, and scientist, and this combination of talents in [illegible] man proves that science and letters need not be di[illegible]. It is a melancholy thing to observe with what d[illegible]ste many literary men regard what they call science, and how they associate with it all that is degrading and unrefined. Goethe stands out a grand example that there is no necessary antagonism between the two; and now we have Holmes, a living man, who possesses to a large extent a knowledge of all the material facts belonging to man's nature, whilst he, nevertheless, can carry them into the higher regions of poetry and religion. He himself is aware of this feeling which exists amongst men of letters and poets, for in his "Life of Emerson" he speaks of poets looking askance at science, and how Emerson contrasts learned men with their glasses with the sons of nature, much to the disadvantage of the microscopic observers. Holmes says that he notices the poet is curious and asks all manner of questions but never thinks of waiting for the answer, still less of torturing nature to get at it. Emerson wonders, for instance, when looking at flowers, "why nature loves the number five," but leaves his note of interrogation without troubling himself any further. Wendell Holmes shows that this might have been answered without any loss to his poetical mood, for, speaking of a character in "The Guardian Angel," he says: "It seemed as if nothing of all that he met in his daily life was uncommon or unclean to him, for there was no mordant in his nature for what was coarse or vile, and all else he could not help idealising into its own conception of itself, so to speak. He loved the leaf after its kind as well as the flower, and the root as well as the leaf, and did not exhaust his capacity of affection or admiration on the blossom, upon which his friend the poet lavished the wealth of his verse." No writer that I am acquainted with can combine like Wendell Holmes the real facts of nature with all which religion or poetry is craving after. He can describe the burial of the young girl under the tree, together with the decomposition of the body, and the further chemical changes which tend to the growth of the plant; and with this he does not hide ideas which might suit the believer in metempsychosis or the Christian:—

> "At last the rootlets of the trees
> Shall find the prison where she lies,
> And bear the buried dust they seize
> In leaves and blossoms to the skies:
> So may the soul that warm'd it rise."

Probably all that I have said and all the quotations which I have given are known to the admirers of Wendell Holmes, but there are many I find in our profession who are less acquainted with his works, and are ready to applaud because one amongst their number has distinguished himself outside medicine in the walks of literature. It is, however, because he has combined two professions, or rather made use of his medical learning in the portraiture of character, and thus in my opinion elevated the standpoint of the novel writer, that his superexcellence is seen. In this respect Dr. Oliver Wendell Holmes stands unique. I have no hesitation in stating my belief that the raciness of his writings with the subtlety of thought comparable

only with "Tristram Shandy," as being ever [illegible] will make them always live. The man him[illegible] been the subject of love and affection. The wo[illegible] Laureate might well apply to him:—

> "A life that all the muses deck'd
> With gifts of grace, that might express
> All-comprehensive tenderness,
> All-subtilising intellect."

CALCULUS IN A CHILD, REMOVED BY SUPRA-PUBIC CYSTOTOMY, FOLLOWED BY PRIMARY UNION.

BY ROBERT WILLIAM PARKER,
SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

THE following case seems worthy of record at a time when supra-pubic cystotomy is again on its trial. The little patient first came under my observation at the hospital in February last: he was then suffering from severe whooping-cough. Although his stone symptoms were very marked and sometimes painful, I thought it wise, nevertheless, to postpone the operation until the cough was better. In part perhaps [illegible] to the long cold winter, little or no improvement in the cough took place until towards May; then it began to diminish, and on June 1st he was admitted. At this time he was a small, rickety, undergrown, anæmic child, just under three years of age, and could hardly walk. He was a native of the neighbourhood. For ten months past he had been noticed to pull at the prepuce a good deal; for seven months there had been increased frequency in micturition, with some straining during the act, but never any sudden arrest in the flow. The urine was said to get "thick on standing, to be often offensive, and never to have contained any blood." After his admission the urine was found to have a neutral reaction, and on standing threw down a considerable sediment of urate of ammonium. There was no albumen, and the urine was not offensive.

On June 4th, the usual preliminary enemata having been previously carried out, I performed supra-pubic cystotomy. The rectum was inflated with an indiarubber bag, the bladder distended with a warm solution of boric acid and retained by an elastic ligature placed round the root of the penis. The bladder was quickly reached and exposed through a median incision; a curved needle was passed through its coats on each side of the median line armed with silk, which was then used to raise and steady the bladder, and in some measure to retract the orifice of the incision which was now made into it with a small scalpel. The stone was quickly withdrawn by means of a small lithotomy forceps. After this, the cavity of the bladder was explored with the finger to make sure that it was empty. A catheter was passed through the urethra, and a quantity of warm boracic solution injected in order to wash out any blood-clots and for the purpose of thoroughly purifying the wound. My next care was to carefully close the incision into the bladder; this I did by several sutures of fine chromic gut, after which the silk threads (temporarily put in to hold and steady the bladder) were withdrawn. The bladder now gradually contracted; the edges of the rectus muscles were brought together, and finally those of the incision through the external abdominal wall. A sprinkling of fine iodoform was applied to complete the antiseptic precautions; over this a pad of lint and a quantity of corrosive absorbent wool were fastened on with a flannel bandage. He was given tincture of opium and kept very quiet for some hours after the operation. The dressing, having remained quite dry, was not changed for forty-eight hours. He had passed urine per urethram in natural quantity without effort or pain. On the fourth day after operation, the dressing was again changed. The wound being apparently healed, the external sutures were removed, and a broad band of fenestrated strapping was applied. The urine was of neutral reaction, and did not contain any albumen. The temperature remained normal throughout; the union gradually became firmer, was fully cicatrised in a fortnight, and the boy discharged well on June 20th, sixteen days after the operation.

I report this case of primary union after supra-pubic cystotomy, though it is a solitary case—I might almost say a unique one,—as a sample of what is possible, and what therefore we should endeavour to strive after; while I feel, nevertheless, that this standard is rather too high a one for the generality of cases. In a former case, operated upon two or three months ago, I carefully closed the external incisions, putting a soft catheter through the urethra into the bladder with the intention of keeping the bladder quite empty and contracted, in the hope that thus the wound into its walls would close spontaneously. But I was disappointed; the vesical wound did not close, as urine began to dribble through it within a few hours. Besides this, the temperature rose to 102° F., and remained high, and the boy was very restless and uncomfortable. I attributed all this to the presence of the catheter, their disappearance on its withdrawal confirming this view. The case subsequently did very well; the incisions healed by granulation, but upwards of a month elapsed before they were quite repaired.

It appears to me, in the light of these cases, that when the tissues are healthy, as in these young subjects, an attempt to secure primary union should be made by carefully suturing the bladder, by a judicious use of sedatives, and by abstaining from all interference with the urethra. A catheter in the urethra causes as much irritation in a child as in an adult (a fact I had not sufficiently considered in my first case), and brings about those conditions, fever and restlessness, which are almost incompatible with primary union. Moreover, the mechanism of micturition seems to be interfered with. The boy, in whose case I left a catheter in the urethra, did not pass any urine per urethram for many days after the catheter had been finally discarded. Whereas in the case now under notice, thanks to the closed bladder and the absence of irritation, urine was voided normally from the first.

It may be asked why I discarded the old-established operation in favour of a new one, still on its trial. I can only reply that, in my judgment, the new operation has very much in its favour to recommend its general adoption: the high operation can be performed without danger to any important structures, whereas lateral lithotomy, even when done with anatomical accuracy, is a "leap in the dark," and cannot be performed without cutting in the close proximity of very important physiological structures one or other of which may possibly be wounded. I am not aware that primary union after lateral lithotomy has ever occurred, even by chance. If this case of mine proves to be a solitary one, it nevertheless shows what is possible after supra-pubic cystotomy. I was ably assisted at the operation by the resident medical officer, Mr. Battams; and I am indebted also to Dr. Richards, resident clinical assistant, for anæsthetising the patient and for his careful record of the case.

Old Cavendish-street, W.

A CASE OF

TRAUMATIC STRICTURE OF THE URETHRA, TREATED BY INTERNAL URETHROTOMY AND CONTINUOUS DILATATION.

BY C. YELVERTON PEARSON, M.D., F.R.C.S.E.,
PROFESSOR OF MATERIA MEDICA IN QUEEN'S COLLEGE, CORK; ASSISTANT-SURGEON TO THE NORTH CHARITABLE INFIRMARY AND CITY OF CORK HOSPITAL, ETC.

OWING to the few cases recorded in which the operation of internal urethrotomy has been undertaken for the relief of traumatic stricture, and the remarkably successful result which followed its performance under what I think may be regarded as rather unfavourable circumstances, I am induced to believe that the following case is one which will be read with attention by those who take an interest in urethral surgery.

C. T ——, aged twenty-six, boiler-maker, presented himself on Aug. 17th, 1885, at the out-patient department of the North Charitable Infirmary. On the afternoon of the previous day he had fallen from a plank a distance of over four feet and came astride an iron bar. Immediately after the injury blood flowed freely from the urethra, and continued to do so for some time afterwards; he also passed very bloody urine each time he micturated. On examining the perineum, it was found to be slightly ecchymosed, as was also the [illegible] of the scrotum. There was no tume-

faction or other evidence of urinary extravasation. Since the accident occurred there had been no difficulty in passing urine, but the act of micturition was attended with considerable pain, and was both preceded and followed by urethral hæmorrhage. I arrived at the conclusion that the patient was suffering from partial laceration of the urethra. I ordered him to be immediately admitted into hospital, and (as the surgeon for the day had left) gave instructions for him to have a warm bath, and a draught containing twenty minims of sedative solution of opium and ten minims of tincture of belladonna, to be repeated every six hours; also, in case retention occurred, to have a No. 10 gum-elastic catheter (with stilet) passed, and tied in.

On arriving at the hospital the following morning, the clinical clerk informed me that on the previous evening, owing to retention, the instrument had been passed, but was removed when the bladder had been emptied; its use had not been attended with any difficulty or hæmorrhage, and the patient, finding himself subsequently able to pass urine free from blood, had (much to my astonishment) left the hospital early that morning. I naturally anticipated that he would reappear on some future occasion. In this I was not mistaken, as he came to my house on Sept 22nd, complaining of great difficulty in passing urine, and said there was much diminution in the size of the stream, which conditions were becoming rapidly more marked during the past week. On endeavouring to pass a No. 6 English gum-elastic instrument, it was abruptly arrested at the bulbous portion of the urethra. I now tried various instruments of smaller size, and ultimately succeeded in passing a No. 4 French bougie (about No. 1 English), and this was tightly grasped. I now informed the patient that his condition required prompt and careful treatment, and strongly urged him to go into hospital and submit to an operation; this he refused to do, as he said he was engaged at some special work, which he would lose if he did not return to it immediately; he, however, promised to come to me twice a week to have instruments passed, but could not do so more frequently, owing to his business being at a considerable distance. He continued to attend for a few weeks, and I succeeded in increasing the calibre of the stricture to No. 7 French (between 2 and 3 English), but could not get beyond this. I also noticed that the instrument passed with great difficulty through the membranous portion of the urethra. He now said that he had much inconvenience in attending, but could continue to do so once a week. I told him that I did not think the occasional passage of instruments would improve his condition any further, and that he must ultimately submit to an operation. I also gave him Nos. 5 and 6 French bougies, which I instructed him how to pass for himself every other day. He continued this mode of treatment up to the middle of November, when, owing to his contract being fulfilled, he "went on the spree," and came to me on the evening of Nov. 26th, suffering from retention, great pain, and an over-distended bladder. I endeavoured to pass an instrument of the smallest size, but was unable to do so. I then gave him a note to the house-surgeon of the North Infirmary, ordering a warm bath and full opiate, and saying that, if he failed in relieving him, I should be sent for. The house-surgeon, not finding the above measures succeed, tried to pass a fine catheter, but could not do so, and, not wishing to disturb me at such a late hour, tried a second bath; this proved successful, but the patient, finding himself able to pass urine in the morning, left the hospital. He again took drink and reappeared in the afternoon suffering from retention, when he had a warm bath, and while in it a fine catheter was passed and tied in; the patient, however, removed it himself in the morning and again left the hospital. He came to my study in the afternoon and inquired into the nature of the operation that I had recommended. I strongly urged him to have Syme's operation performed, but he strongly objected to any such severe measure. I then explained to him that an *internal* operation might be done, but I could not guarantee such a successful result as I anticipated from the former. He consented to submit to internal urethrotomy, but disliked so much remaining in hospital that I undertook to perform it at his own home. Being anxious, if possible, to divide the stricture from behind forwards, I determined to first try continuous dilatation for a few days. On Nov. 30th I accordingly tied in a No. 3 French catheter, which was the largest I could pass. As the urine did not flow freely enough through this, the patient had to remove it during the night. On the following day [illegible] No. 1 English gum-elastic; on Dec. 2nd I chan[illegible]ge[illegible]r a No. 3; on Dec. 3rd I got in a No. 5, and prom[illegible] operate the following day, as the subject of my treatm[illegible] was getting highly impatient at the delay.

Operation.—On the morning of Dec. 4th, the patient being fully under the influence of chloroform, I first tried to pass a No. 6 catheter, but could not, showing that the No. 5 had effected little or no dilatation since the previous day. I then introduced Sir H. Thompson's modification of Civiale's urethrotome, and passed it through a short stricture situated in the anterior part of the bulb, but was unable to get it through a second one, commencing probably at the junction of the membranous with the bulbous urethra. On withdrawing the instrument one-third of an inch, it was arrested by the anterior stricture; this I freely divided from behind forwards. I now introduced the staff of a Teevan's urethrotome, and then, as urine appeared from the groove, passed down the concealed blade to the seat of stricture. This I attempted to divide, but at first failed to do so, the stricture apparently being pushed backwards by the instrument, notwithstanding that the penis was kept on the stretch. I then directed my assistant to extend it still more forcibly, and after another trial succeeded, though great force had to be employed, the stricture cutting like cartilage. On withdrawing the instrument there was a moderate amount of hæmorrhage, which soon ceased. Finding the meatus congenitally contracted, I incised it, and then [illegible] pass a large curved metalic sound, but failed to get it through the membranous portion. I again introduced Thompson's urethrotome, and this time it passed readily through the second stricture, which I now divided on the floor from behind forwards. I again attempted to pass the large metallic sound, but could not do so. I also failed to pass a large-sized elastic catheter. Not having intermediate instruments at hand, I introduced a No. 6 English gum-elastic catheter, and tied it in. A half-grain morphia suppository being placed in the rectum, the patient was put to bed, and ordered a draught containing fifteen minims of sedative solution of opium, to be given in six hours after, and to be repeated every sixth hour if necessary.

The following day (Dec. 5th), finding the patient in a most satisfactory condition, able to urinate easily through the catheter, and that no urine flowed by the side of it, I determined to leave it undisturbed. Dec. 6th: Withdrew the No. 6, and introduced a No. 8, without encountering the slightest difficulty or obstruction. 7th: Removed the No. 8, and passed a No. 10 with great ease.—9th: Removed the No. 10, and passed a No. 12 quite easily.—11th: Removed the No. 12 catheter. I now passed in succession three conical metallic sounds, Nos. 14, 15, and 17, English size; these all passed quite readily, and with neither of them was the slightest obstruction felt at the seat of stricture; No. 17 was, however, a tight fit at the meatus. The patient was now left, for the first time since the operation, without a catheter, and was permitted to get up the following day; the metallic sounds being again passed; these were also used for the next few days. He was then provided with Nos. 23 and 25 French gum-silk bougies, which he was instructed to pass daily for a time, then on alternate days, and gradually to increase the interval to two or three days; he was also strongly warned of the evil of the intemperate habits to which he had been previously addicted. I should mention that the progress of the case was not attended with any constitutional disturbance, the temperature never having risen above 99° F.

Subsequent history.—The patient came to me a few times during the few weeks following the operation to report favourable progress, but was not again seen by me since the end of last December until the eve of writing this paper—viz., March 23rd, 1886,—when he came at my request, so that I might ascertain his condition. He then informed me that he had continued to pass the instrument at intervals varying from two to four days, that he had not experienced the slightest difficulty in micturition, although he had on several occasions partaken very freely of stimulants. I passed a No. 23 French bougie without difficulty, though it was slightly grasped during withdrawal. I also passed a No. 20 metallic bulbous exploring instrument, with which I was able to detect the previous sites of both the strictures. I made no further examination.

Observations.—I have described the foregoing case, not with the object of advocating the operation of internal urethrotomy in cases of *traumatic* stricture, but rather as an illustration of the amount of good that may be derived

from it, and also because it has been so rarely proposed and taken in such cases. Although I am pretty extensively acquainted with the literature of urethral surgery, I do not at this moment recall a single recorded instance where internal urethrotomy has been performed for traumatic stricture. This case was one related by Mr. Teevan and reported in the Proceedings of the Clinical Society of London, in which both an old-standing traumatic stricture and several penile fistulæ were cured by the operation. In the case I have related, had I the option of choosing, I should have preferred performing either Syme's operation or a *combination of internal and external urethrotomy*, such as advocated for some cases of stricture by Dr. Otis, and also by Mr. Reginald Harrison. It may be asked why I did not at once after the operation succeed in introducing a large instrument. To this I can only answer by offering the explanation which presented itself to my mind at the time—viz., that although I had divided the stricture, the cicatricial ring still remained in such an unexpanded condition that it would not admit the end of a large instrument, just as would occur with a metallic ring when cut at one place. Having formed this opinion, I determined to carry on the process of *continuous dilatation*, and insert between the divided ends what has been aptly termed by Gouley "a cicatricial splice," as a jeweller would enlarge a finger-ring by the introduction of a new piece of metal, the effect in both cases being to permanently enlarge the diameter of the circle. In conclusion, I may point out that the patient's habits, inclinations, and dislike to remaining in bed were serious obstacles to the course of treatment; and, on the whole, it is rather surprising that such a successful result has been attained.

P.S.—At the time of correcting the proof of this paper—viz., June 29th, 1886—I find upon inquiry that the patient continues in the same satisfactory condition as when last examined by me.

OBSERVATIONS WITH REFERENCE TO THE THEORY OF THE RESPIRATORY MURMUR,

AND THE SEAT OF ORIGIN OF THE SO-CALLED VESICULAR MURMUR, IN A CASE IN WHICH THE LARYNX WAS EXTIRPATED BY DR. NEWMAN.[1]

BY JOSEPH COATS, M.D.

BY the kindness of Dr. Newman I have had the opportunity of making some observations on a patient of his, chiefly in regard to the origin and propagation of the laryngeal and pulmonary auscultatory phenomena. In the first place it may be well to state the points which these observations were intended to bear on.

A very excellent summary of the principal facts bearing on the causation and mode of production of cardiac and respiratory murmurs is given by Hilton Fagge, first in an article in the *Medico-Chirurgical Review* for July, 1873, and again in his book on "Practice of Medicine," recently published. It is now generally believed that the various cardiac and vascular murmurs are produced by what is technically called a *veine fluide*. When a jet of fluid, whether liquid or gas, issues from a narrow space into a wide one, a blowing sound is produced, the form which the fluid takes under such circumstances constituting the *veine fluide*. So far as the larynx and trachea are concerned, the conditions for a blowing sound are fulfilled at the glottis, where, both in inspiration and expiration, the air issues from a narrow aperture into a wider space. We have accordingly at the glottis a loud blowing sound both with inspiration and expiration. In regard to the more remote parts of the respiratory tract, there is only one place where the due conditions are present, according to the theory, for the production of a *veine fluide*, and that is where each minute bronchiole opens into the somewhat wider infundibulum or group of air vesicles. During inspiration the air passes here from a narrower tube into a somewhat wider space, but during expiration it does not do so. The obvious conclusion that the normal respiratory murmur, which is essentially a sound of inspiration, has origin in a *veine fluide* occurring in the multitudinous infundibula, has not remained unchallenged. It has even been asserted that the sound does not originate in the lung at all, but is propagated from the larynx. This view seems to have been first asserted by M. Beau, and since his day the controversy has ranged around that point, with a general result unfavourable to his views. It seems to be a law of the *veine fluide* that the sound produced is most easily propagated in the direction in which the fluid is moving. According to this law, the expiratory glottic sound should not be audible over the trachea, whereas, as a matter of fact, it is usually louder than the inspiratory. Bergeon explains this on the ground that the false cords and the base of the epiglottis form a kind of lip or rim, under which circumstances, as experiment has shown, the sound may be projected backwards against the current, just as a regurgitant aortic murmur is propagated against the current, and is audible over the aorta. It will appear from our observations that this explanation hardly holds.

Turning now to these observations, I may describe briefly the local conditions. The larynx had been removed, and in its place there was a tube formed of vulcanite. This tube is about half an inch in diameter, being nearly that of the trachea, and it forms, in fact, a direct continuation upwards of the trachea, its lower orifice being embedded in the mucous membrane, so that there is no sudden alteration of calibre. The tube fixed in the upper end of the trachea is bent forward and emerges from the wound in the neck with an open mouth, retaining its full diameter throughout. By this means the trachea is continued outwards without the interposition of the larynx or the parts above it, and continued virtually in its full calibre. From the upper side of this tube a shorter and narrower one proceeds into the pharynx, and the patient can breathe through this tube when the large outer one is closed. This smaller tube I shall call the pharyngeal tube, the larger being the tracheal. By slight alterations in this apparatus I was able to obtain three different conditions, and to study the changes in the auscultatory phenomena produced thereby. These were—(1) The tracheal tube wide open with the pharyngeal tube open or closed, so that breathing was carried on essentially by the wide tracheal tube; (2) the tracheal tube closed and the pharyngeal one open, so that breathing was carried on through the narrow pharyngeal tube; (3) the tracheal tube partially closed by a stopper, through which was passed a much narrower tube, so that breathing was carried on through this narrower tube.

1. The tracheal tube open, and breathing carried on through it—a condition equivalent to the elimination of the larynx and buccal cavity. In Hilton Fagge's paper already alluded to experiments are referred to by Bergeon and Boudet in which the trachea of a horse was cut across and drawn forward out of the body, so as to eliminate the larynx, as in our observations. They assert that as a result the glottic murmurs disappeared entirely, this being quite consistent with the view that they originate in *veines fluides* at the glottis. My observation scarcely agrees with this, however. A loud expiratory blowing sound was produced at the external orifice of the tube, so loud as to be audible at some distance from the patient. There was here obviously the precise condition for the development of the *veine fluide*—namely, a tube opening into a wide space, the sound being similar to that produced when we form with the lips a round aperture and blow through it, and having obviously a similar mode of origin. This loud expiratory sound was propagated down the trachea and apparently to the larger bronchi. Auscultation in the supra-sternal notch and directly over the trachea revealed a loud blowing expiratory sound and a very feeble inspiratory one. The results of auscultation over the root of the lung behind were very interesting. It was found that the difference in intensity between the expiratory and inspiratory sounds had become much less, so that the conditions resembled those of ordinary bronchial breathing, the expiratory being as loud or almost as loud as the inspiratory sound. There was, however, a marked difference in quality in the two sounds, the expiratory retaining the blowing tubular character, while the inspiratory partook rather of the quality of the vesicular murmur. It may be inferred, I think, that the equalisation of the two sounds as regards intensity was largely due to the inspiratory becoming reinforced by the normal vesicular murmur, and

[1] This paper was read at the Pathological and Clinical Society on May 11th, 1886, and as the observations seemed to be of importance in relation to the origin of the respiratory murmurs, a committee was appointed to go over the points with me, and to report. The committee consisted of Professor Gairdner, Dr. Newman, Dr. J. Lindsay Steven, and myself, and the report is here added to the original paper.

this would already indicate that the vesicular murmur originates in the pulmonary parenchyma. This was confirmed by auscultation over other parts of the lung, particularly in places where the respiratory murmur is normally well heard and characteristic, such as the lateral region beneath the axilla. The sound had the usual characters of the vesicular murmur, the inspiratory phase being distinct and prolonged, while the expiratory was scarcely audible. It seemed obvious that the expiratory sound produced at the orifice of the tube, although conducted freely to the parts of the chest most nearly in contact with the root of the lungs, was damped by the pulmonary parenchyma, and therefore inaudible over the periphery of the lungs.

2. The tracheal tube plugged and the pharyngeal one open, so that breathing was carried on through the narrow pharyngeal tube. We have here almost the precise conditions of laryngeal breathing. The lower orifice of the pharyngeal tube opening into the wider tracheal tube affords the conditions for a *veine fluide* during inspiration, while the upper orifice of this tube opening into the pharynx gives the conditions for a similar sound during expiration. Auscultation of the trachea gave the usual characters of tracheal breathing—namely, loud expiratory and inspiratory murmurs, nearly equal in intensity and duration. At the root of the lungs behind there was the usual bronchial breathing, and over the rest of the lungs the regular vesicular murmur.

3. A narrower tube inserted into the orifice of the wide tracheal tube. Here we have again the conditions for a *veine fluide* at the internal orifice during inspiration, and at the external orifice during expiration. Auscultation over the trachea showed that the inspiratory sound was much louder than the expiratory, the sound originating at the inner orifice of the tube being better carried than that originating at its outer orifice. The sounds in this experiment were nearly the converse of those with the tracheal tube wide open, in which case, as already mentioned, the expiratory sound was much louder than the inspiratory. A very striking contrast was produced when during auscultation with open tube the latter was suddenly stopped by the plug bearing the smaller tube, the inspiratory sound in the one case closely resembling the expiratory sound in the other, both in quality and intensity. The results over the root of the lung and elsewhere were somewhat similar to those in No. 2.

Looking to these observations as a whole, we seem to be led to the following conclusions. First, the sounds produced at the glottis or larynx are freely conducted by the dense tissues comprising the trachea and bronchi, and are thus audible wherever these hard structures are in such a position as to carry the sound to the surface. In this way they may be communicated in the opposite direction to the current of air, so that the expiratory sound is audible down the trachea and at the back, where the root of the lung is nearest to the surface. It may be inferred that bronchial breathing generally is due to conduction by more or less solid tissue. Second, the vesicular murmur takes origin in the extreme distal part of the respiratory apparatus. In all the forms of the experiment the characters of the respiratory murmur proper remained unchanged, and even when at the root of the lungs there was a loud expiratory sound, this was not communicated over the general surface of the lungs. It does not lie within the scope of our subject to consider the exact mode of origin of the vesicular murmur, whether by the *veine fluide* in the multitudinous infundibula or by some other method, but the seat of origin seems sufficiently indicated by these observations.

I made also some observations as to the propagation of the voice produced in the artificial larynx, but without any result worthy of note. I would only remark that when the patient breathed with the voice-reed in position without vocalisation the respiratory murmur was exceedingly feeble or absent, evidently because little air could obtain passage by the sides of the reed. Indeed, so little passes that he can only wear the reed about ten or fifteen minutes continuously.

Report by a Committee of the Glasgow Pathological and Clinical Society.

"The committee having considered and carefully gone over the whole of the facts set forth in Dr. Coats' report, agree to adopt it as their report. In particular, the committee are quite satisfied as to the bearing of these facts on what is by far the most important question involved—viz., the origin of the so-called vesicular murmur, and that it must be co[illegible] be perfectly well established that the presen[illegible]nce of a glottis or of any corresponding arrang[illegible]ling a *veine fluide* at the anatomical site of the lar[illegible]ables influence whatever in the production of the nor[illegible]icular murmur.

W. T. GAIRDNER, JOHN LINDSAY STEVEN,
DAVID NEWMAN, JOSEPH COATS.

"May 26th, 1886."

ON A CASE OF IMPERFORATE ANUS.

BY SIR WILLIAM MAC CORMAC.

THE particulars of this case may be worthy of record, as illustrating a practice somewhat different from that usually adopted.

On March 21st, 1886, I was requested by Dr. Duncan, of Henrietta-street, to see a child born two days previously. The anus was well formed, but almost immediately terminated in a pouch about half an inch beneath the surface. On careful and repeated examination, no trace of impulse or proximity of the bowel could be made out. We decided, therefore, that it was preferable to perform colotomy in the left groin, rather than undertake what promised to be a hopeless search for the bowel in the natural situation. A small incision was made in the usual place, and after the structures had been divided in succession, the intestine at once presented in the wound; it was sutured to the skin, and afterwards opened. Meconium escaped, and the abdominal distension, which before was very considerable, shortly subsided. The operation created no disturbance; the child took its food eagerly, slept well, and there was no sickness. The intention was at a later period to pass a probe or blunt instrument from the opening in the sigmoid flexure downwards towards the anus, and in this way ascertain the condition of the rectum, to what extent it might be deficient, and how far distant it terminated from the external cul-de-sac. On April 12th this was accordingly done, and, contrary to expectation, only a quite thin septum was found to exist between the rectum and the anus. It was divided with great ease upon the rounded extremity of a director, which was caused to project, and a free opening established, a well-perforated drainage-tube being subsequently passed from one opening to the other to facilitate the bowel being washed out, and to prevent the opening into the groin closing, which it showed a disposition to do. The child made an equally good recovery from this operation, and continued perfectly well for some days; then symptoms of acute peritonitis suddenly set in, and it died on April 17th.

On examination after death, there was a considerable amount of lymph and fluid in the abdominal cavity. The upper portion of the sigmoid flexure had been opened, and was firmly attached to the abdominal wall. The rectum was found full of a semi-solid mass of fæcal matter, evidently of some duration, and this condition no doubt accounted for the total absence of impulse in the region of the anus. The rectum was found to be complete, with the exception of the septum already spoken of; and there was nothing found in the region of either operation to account for the fatal result. After removing and slitting open the intestine, a small perforation was found in it about mid-way between the opening in the groin and the anus, and resting against this a small scybalous mass of fæces. It was as the result of the ulceration and perforation of the bowel at this point that peritonitis took place.

In those cases which are frequently met with where the bowel terminates at an unknown distance from the anus, the performance of Littré's operation gives the child immediate relief, and is attended by comparatively little danger; time is gained for considering what the next step should be at a time when the child is older and better fitted to bear a further operation; and from the opening in the groin the condition of the extremity of the bowel can be ascertained with tolerable accuracy. When practicable, the natural channel can be re-established, with the great advantage of having an exact guide to the position of the extremity of the gut, an advantage which all will appreciate who have ever had to make the difficult and often fruitless search for the blind extremity of the bowel in cases of imperforate anus.

Harley-street, W.

CASE OF POISONING BY CHLOROFORM.

BY J. G. U. WEST, L.R.C.P. LOND., HON. MEDICAL OFFICER TO THE NORTH STAFFORDSHIRE INFIRMARY.

ON April 6th, at 7 P.M., I was hurriedly summoned to a man aged fifty, a cab-driver, who had been found in his bedroom in an unconscious state. His wife had recently drowned herself, and at the inquest the jury had severely censured him for alleged ill-treatment of her. I found him lying on a bed in a state of deep coma; pupils slightly contracted, and not acting to light; breathing stertorous; complete muscular relaxation; conjunctivæ insensible to touch; pulse 96, regular, but very small. On smelling his breath I detected a very strong odour of chloroform. There was no empty bottle in the room. I at once used the stomach-pump, obtaining four ounces of dark-brown fluid, which did not smell of chloroform. Up to this time I could get no history, but I now discovered that three hours before I saw him he came home from the direction of his stable, and went straight upstairs. I sent a policeman to the stable, where he found an empty bottle, labelled chloroform. The coma deepening, the breathing becoming shallower and more stertorous, and the pulse weaker and more frequent, I thought an antidote was essential, but I could find no allusion to poisoning by chloroform in any book in my possession. Assuming that the great danger was from failure of the heart's action, I thought that atropine would most probably prevent the cardio-inhibitory effect of the chloroform. As he was quite unable to swallow, I injected three quarters of a grain of sulphate of atropia under the skin of the arm at 9 P.M. In twenty minutes the pupils began to dilate, and he moved his arms. The pulse improved, and the breathing lost its stertor. About midnight the conjunctivæ were sensible to the touch, and at 3 A.M. on the following morning he became conscious, and spoke. From this time he continued to improve, though for a few days he suffered from gastro-intestinal catarrh. He confessed that he bought two ounces of chloroform, saying that he wanted it to clean some clothes, that he drank it at the stable without diluting it, and then walked home, a distance of about 250 yards.

Whilst anxious to avoid the *post hoc propter hoc* fallacy, I think the case worthy of record as showing the probability of atropine and chloroform being antagonistic, and the fact of the patient exhibiting no sign of belladonna-poisoning after the injection appears to strengthen this hypothesis.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

CHARING-CROSS HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. J. ASTLEY BLOXAM.)

THE following cases present points of interest. The first case is one in which the result of successful suturing of the patella for recent transverse fracture was noted a long time after the operation, and the result was very satisfactory. In the second, a large tumour resembling a new growth was successfully treated by iodide of potassium, the diagnosis that it was due to syphilis being thus confirmed. In the third the new growth is recorded as scirrhus, but as this is a very rare growth, adenoid or cylindrical epithelium being the usual form of cancer met with in the rectum, we must wait for the further evidence afforded by microscopical examination before agreeing with the diagnosis.

CASE 1. *Transverse Fracture of Patella from Muscular Violence.*—Henry E——, aged twenty-seven, a labourer was brought to the hospital on Jan. 24th, 1883, having fallen downstairs. He says he felt the patella break as he was falling, and did not strike it anywhere. The fragments were widely separated.

Feb. 1st: This afternoon Mr. Bloxam cut down on the joint and wired the two fragments together under antiseptic precautions.—2nd: The patient has passed a good night; there is no elevation of temperature.—9th: The patient appears to be getting on well, and has no pain.—24th: The dressing was removed to-day, and the wound has almost completely healed.—March 6th: The wound is now quite healed. Patient can flex the joint without difficulty. He was discharged on the 20th, with a caution to be careful for some time to come. There was perfect apposition of the fragments. The patient has been seen and examined during the last few days, and the apposition of the fragments is still perfect after an interval of more than three years. Flexion and extension of the knee-joint are quite perfect.

This is an example of the excellent results which have been obtained in a great number of cases by securing that close contact of the fragments which is necessary to osseous union, and which is rarely obtainable by any other method.

CASE 2. *Osseous Tumour of Tibia.*—Margaret H——, aged twenty-nine, housewife, was admitted on August 22nd on account of a hard, dense, pear-shaped swelling on the upper and anterior part of the tibia, situated just below the knee-joint. It was very painful, and in about a fortnight the pain had extended down the leg to the foot. The anterior border of the tibia is very rough in its whole course. There are one or two old scars, said to be the marks of blows or falls. The tumour measures 3⅞ inches in length and 3¼ in width at the upper part. The circumference of the limb over the tubercle is 11¾ inches, as against 11 inches round the other leg; and one inch and a half below it measures 12 inches. The patient says that three years ago she noticed a small hard painful swelling on the left leg, just below the knee. She did not at first pay much attention to it, and ascribed it to the effect of a fall she had had a few days previously. It, however, rapidly increased in size and became more painful, until three months ago, when the pain became very great, the tumour taking on at the same time a further rapid growth. She was obliged to lay up for a few days, during which time the swelling subsided somewhat, and she then applied to the hospital for relief, and was admitted. Her father died of "paralysis of the brain" and her mother of dropsy. One of her brothers died of blood-poisoning. She has four brothers and sisters alive and well. She had a miscarriage at fourteen years of age, and a child a year later, the latter being still living and healthy. She then had another miscarriage, and after that a child, which died when three months old. She has had one child since, still living. The patient says she has never had any illness, nor has her husband. She was ordered a mixture containing ten grains of iodide of potassium three times a day. The swelling to be painted daily with liniment of iodine.

Sept. 3rd: The patient still complains of pain in her leg. The dose of iodide of potassium was increased to fifteen grains. The swelling is a trifle smaller.—7th: The iodide of potassium was raised to twenty-five grain doses to-day. The patient is decidedly improving, but complains that the painting hurts her a good deal.—16th: The application of the iodine liniment is to be discontinued. The tumour is now markedly diminished in size, and the pain is nothing like so severe.—24th: The patient left the hospital at her own urgent request, although she acknowledged that she was rapidly improving.

This case offered an example of the efficacy of large doses of the iodide where smaller doses had failed to afford relief. There is no reason to doubt that had the patient continued under treatment absorption might have been brought about and the tumour dispersed.

CASE 3. *Scirrhous Cancer of the Rectum; Colotomy; Recovery.*—Joseph D——, aged fifty-three, a publican, applied for relief on account of passing blood with unformed motions, together with an aching and heaviness in the rectum after defecation, which, moreover, does not relieve the desire. He was admitted on Jan. 8th, and on examining the rectum healthy mucous membrane and a normal calibre were felt for about four inches; at that point some thickening and induration were present, chiefly of the posterior and left walls. On passing the finger beyond this, an abrupt edge can be felt, followed by an irregular excavation, which seems to become lost in the gut higher up. The

patient says that three months ago he first passed small clots of blood mixed with slime, unaccompanied by a motion proper; when he did succeed in passing a motion, he noticed that it was flat, tape-like, generally with a smear of blood down one side. For the last two months, however, the motions have been without form. He has lost flesh markedly for the last two months. He had inflammation of the lungs nine years ago, and kidney trouble six years since, which lasted a week. Six months ago he was troubled with rheumatic pains in the right shoulder, which have not left him. His father died at seventy-five years of age, and his mother at seventy-eight, having had twenty-three children. No history of carcinoma anywhere. On the 24th Mr. Bloxam performed colotomy by means of an incision four inches long, the centre of which corresponded to the centre of a line drawn vertically from the crest of the ilium to the last rib, half an inch behind the middle point of a line connecting the anterior, superior, and posterior spines of the ilium. The direction of the incision was obliquely transverse. A search with the fingers in the abdominal fat readily brought the colon to the orifice of the wound, and it was then secured and opened in the usual manner. Drainage-tubes were inserted above and below, and the ends of the wound sewn up and dressed with a simple pad of antiseptic tow and a bandage. The operation was followed by a good deal of collapse. A considerable amount of fæces escaped during the night.—29th: The temperature has been at 100° yesterday and to-day, and the patient looks weak and exhausted.—Feb. 4th: The patient looks much better to-day, but his temperature is still about 100°. The wound has a healthy appearance, but the mucous membrane shows a tendency to protrude.—20th: He has no pain at present, and sleeps well. Appetite improving. The patient was discharged on the 25th, very much better in health and comfort.

SUSSEX COUNTY HOSPITAL.

CASE OF RECOVERY AFTER SWALLOWING A FLUID OUNCE AND A HALF OF COMMERCIAL HYDROCHLORIC ACID.

(Under the care of Dr. H. Ross.)

For the following notes we are indebted to Dr. Robert Black, house-surgeon.

George B——, a man, aged thirty-nine, was brought to the hospital reported to have swallowed a dose of hydrochloric acid. It appeared that he had lately become melancholic, and had attempted suicide by laudanum four days previously, but was fortunately discovered and the poison taken from him. On the day of admission he purchased an ounce and a half of "spirits of salt," which he sent for in a small gallipot; he then filled an ounce and a half bottle with the acid and drank the whole of it. He was seen about ten minutes afterwards by Dr. Harris Ross, who at once administered some calcined magnesia and recommended his removal to the hospital.

On admission he was very pale and much collapsed. There was much retching, and he vomited a quantity of dark, blood-stained fluid with a peculiar almost aromatic smell. There was a well-marked red line at the back of the hard palate, where the acid had first come in contact with it. He complained of no pain and no tenderness at the epigastrium. He was ordered some carbonate of potash and borax with Battley's solution of opium, but continued to vomit dark blood-stained fluid with small shreds of membrane.

May 4th.—The man has been quite free from pain and can swallow well, but is still sick from time to time. The bowels have acted without aperient, and the motions contain a little blood. A white membrane has formed on the dorsum of the tongue, and is slowly peeling off. He has now a good healthy colour in his cheeks, and presents a tranquil, comfortable appearance, and sleeps well all night. The temperature has been 99·5° until to-day, and is now normal.

10th.—The patient has been up for two days, and appears perfectly well. There is no pain, no difficulty in deglutition, and the evacuations contain no blood. There has never been any marked constipation.

On the 12th he left the hospital quite well. Dr. Ross ascertained from the chemist that the acid supplied was of the ordinary strength of the commercial crude hydrochloric acid; and it was conclusively proved that the full amount above mentioned was taken.

CARDIFF INFIRMARY.

A CASE OF [illegible]IC GOITRE TREATED BY "SHELLING OUT."

(Under the care of Dr. C. T. VACHELL.)

WE are indebted for the following notes to Mr. William Duff.

Annie Z——, aged twenty-three, married, was admitted on July 23rd, 1885, suffering from a tumour on the right side of the neck. She had enjoyed good health until five years ago, shortly after marriage, when a swelling commenced to form over the right side of the thyroid gland, and continued slowly and persistently to enlarge. She had one child a year and a half ago, but neither pregnancy nor lactation seemed to influence the growth. On admission a tumour about the size of a cocoa-nut occupied the position of the right lobe of the thyroid gland, and passed somewhat over to the left of the middle line of the neck. The skin, with a few enlarged subcutaneous veins, was freely movable over the swelling, which moved with the trachea in the act of swallowing. Fluctuation could be felt all over it, more distinct in some parts than others. Neither breathing nor swallowing was seriously interfered with. About three weeks before admission a teacupful of bloody serous fluid was withdrawn by a trocar and cannula, and the tumour was considerably reduced in size, but reaccumulation took place in a day or two. By August 11th the tumour had attained a larger size than ever, the circumference of the neck being 17½ in. The patient was informed that if the tumour remained serious results might ensue, and she consented to an operation.

Ether having been administered, Dr. Vachell proceeded, on Aug. 12th, to remove the tumour under the carbolic spray. A vertical incision measuring about 2½ in. long was made through the skin over the most prominent part, and at once the surface of the tumour came into view, the capsule of the gland, if present, having been so thinned by pressure as to present no difficulty. Up to this point very little hæmorrhage had occurred. Without much difficulty the tumour was now shelled out, but the hæmorrhage which commenced with this process, and continued throughout, was very profuse. Firm pressure was maintained by an assistant, the surface was mopped with very hot water mixed with tincture of iodine (1 in 20), and as bit by bit the surface was exposed all the bleeding points were ligatured. The edges were then brought together, and a drainage-tube inserted.

After the operation the progress was satisfactory. Some sickness in the afternoon and a troublesome cough led to considerable oozing, necessitating the dressing of the wound in the evening. The dressing was repeated the next day. On the 14th the tube was shortened, and on the 16th the stitches were removed. On the 19th boric dressing was substituted, and on the 24th the patient left the infirmary.

The temperature rose on the evening of the day of the operation to 103·8°, and remained more or less febrile till the 19th. Probably this was due to an attack of bronchitis, from which she then suffered.

The tumour, which was irregularly ovoid in shape, measured 13 in. by 9 in., and weighed 20 oz. On being cut into, 9 oz. of dark sanguineous fluid escaped, similar to what had been removed by tapping, but darker. The walls varied from one-sixth of an inch to rather over half an inch in thickness, and consisted of material resembling heart muscular fibre in naked-eye appearance. The internal surface was much and deeply corrugated.

A MUNIFICENT RUSSIAN NOBLEMAN.—Count Orloff Davidoff appears to be a most munificent benefactor to the sick poor of Russia. He recently gave £24,000 for the purpose of endowing a children's hospital dedicated to St. Olgar, in Moscow, which he had built at his own expense, besides buying a house for the purposes of the administration of the hospital, costing £4000. This noble foundation he has now further enriched with a gift of another £24,000. Dr. Chernoff, privat docent for children's diseases in the St. Petersburg Military Medical Academy, has been appointed medical officer to the new institution, which is considered by the Russian medical press as an excellent choice. How much more satisfactory will it be to the munificent donor to be able to watch the success of his hospital than merely to leave part of his money in his will to be devoted to charity after his death.

Medical Societies.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on May 6th, Dr. J. H. Ross, Vice-President, in the chair.

Destruction of Parotid.—Mr. N. P. BLAKER brought forward a woman of over middle age, in whom both parotid and both submaxillary glands had sloughed away after acute inflammation that resembled ordinary "mumps"; there was some dryness of mouth, but no marked inconvenience.

Myelitis, or Reflex Paraplegia (?).—Dr. BLACK showed for Dr. Withers Moore, a man of fifty-three, admitted into the County Hospital with partial loss of motor power in the legs, and of control over the bladder and rectum; most of the reflexes were exaggerated, the gait was stiff and spastic, but there was no marked wasting, and no rigidity; the urine was alkaline, and free from albumen; there was much vesical pain; there was no stricture, but chronic dysuria, and retention, requiring the catheter, had occurred seven weeks before; about the same time he rather suddenly lost power in the legs. On the other hand, in favour of the syphilitic origin of the symptoms (from a disseminated myelitis) was the history of chancre and secondary symptoms two years previously. He was ordered one grain of mercury with chalk three times a day, and from five to ten grains of iodide of potassium; the bladder to be washed out daily with boracic acid solution; and under this treatment all the symptoms had improved in a few weeks.

Congenital Dislocation of both Thighs.—Dr. BLACK also showed for Dr. Withers Moore a boy of ten years with this deformity. He was born by the breech after protracted labour, and never walked properly. His pelvis seemed broad and of female type; the thighs approximated and were shorter than the legs below the knee; the trochanters were near the anterior superior spines of the ilium and two inches above Nélaton's line; the gait was waddling, and there was much lordosis. Sayre's jacket had been applied four years before at another hospital without benefit.

Lichen Ruber Planus.—Dr. MACKEY brought forward a characteristic case of this kind in an adult male, with red flat papules, some umbilicated, confluent over face, body, part of thighs, and outer aspect of arms, discrete in other places, especially on wrists and hands; most, if not all, were on the site of the hair follicles, and some resembled lichen pilaris, whilst sufficient scaling appeared near the large joints to justify Mr. Hutchinson's term of lichen psoriasis, and to some papules the term lichen pilaris would apply. The attack was acute and of a few weeks' duration, and accompanied with much pruritus and nerve depression, but was now getting better with rest, alkaline baths, and carbolised oil, and internally arsenic.

Suppurative Peritonitis.—Mr. WILLOUGHBY FURNER showed the pelvic organs removed post mortem from a case of suppurative peritonitis; there was a small cyst in one ovary, the other had been removed eighteen months before for cystic disease, the stump having been tied with thick silk, no trace of which was found.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AN ordinary meeting was held on May 7th, Dr. Clifford Allbutt in the chair.

Pasteur's Inoculations.—DR. BARRS reopened the adjourned discussion on Dr. C. Chadwick's paper on Pasteur's treatment for rabies. He pointed out that corroboration was needed on certain points, especially as to the real state of the dogs who had bitten the patients.—Dr. DOLAN said that, while fully appreciating Pasteur's work, he was not prepared to accept his method as proved until control experiments had been performed by a commission. There was evidence to show that in certain cases the dogs which inflicted the bites on the patients treated were not rabid, and further evidence was required. What place was to be assigned to cauterisation in these cases? Were there any statistics to show that such a number had been previously treated without hydrophobia subsequently developing? He gave some statistics on these points. He dwelt on the difficulties of the statistical side of the question. The explanation of the deaths was not scientific. It was said that they came too late. If the Russians who died came too late, then all the Russians came too late. We could not accept a theory which worked two ways—one way for failures, another for recoveries. M. Pasteur limited the time to fifteen days. What was the use of taking over cases where the bites had been inflicted before that time. The microbe theory was the basis of treatment; but here, again, a difficulty arose—how to reconcile this theory with the quantity theory. The rabbits were treated in one way, men in another. On man the injections produced not even an abscess or phlegmon, and were to all appearance innocuous. Inject this virus into the brain of a man—we then have a different result no doubt. The state of the rabbits required confirmation.—Dr. HIME, who had recently returned from Paris, referred to the report of a Commission appointed by the French Government for the purpose, who found that of five ordinary dogs injected in the brain with virus all died of rabies, but of those presented by M. Pasteur as protected none died when treated similarly. The strength of the final injection of virus given to the persons treated was sufficient to cause rabies in a dog in half the ordinary time. With regard to the state of the large numbers of persons presenting themselves for treatment, he remarked that if one person who would have suffered was protected, the practice would be justified.—Dr. FARQUHAR, for personal reasons, had made much inquiry as to the incubation period of hydrophobia, and found that in some cases it amounted to five years.—Mr. MAYO said that of fifteen cases treated in the Leeds Infirmary during the past twelve years, the incubation period had varied from seventeen days to five months, the average being about seven weeks.—Dr. CHURTON said he had found caustic of great use in preventing injury from post-mortem wounds, if applied immediately.—Dr. JACOB thought that on general principles it was advisable that M. Pasteur's experiments should be repeated by an independent authority, and that at present there were great difficulties in the way of accepting the matter as proved. If of the 600 or more patients treated at Paris 100 had really been bitten by rabid dogs, we should expect about six to become affected, and if these escaped a great deal would be proved towards accepting the method.

Static Electricity as seen in M. Charcot's Clinique.—Mr. ROBERTS read a paper on this subject. He described the machine there used and the one he himself adopted, which was by Carré, worked by a hydraulic motor. The patient was insulated and charged, and sparks drawn by suitable conductors from the affected parts. He had found it useful in various rheumatic and neuralgic affections.

Mr. MAYO ROBSON showed a child, three months old, on whom he had operated for Lumbar Spina Bifida by excision of the sac three weeks previously. The child was in good health, with all its movements perfect.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Friday, May 7th, Mr. Joseph White, President, in the chair.

Dr. HANDFORD showed a fœtus (dissected), recently presented to the Society by Dr. Mutch, as an illustration of Maternal Impressions. Dr. Handford also brought forward the following pathological specimens:—1. Hydro-Salpynx, Granular Kidneys, and Hypertrophied Heart, from a woman aged fifty-five. 2. Tumour of the Base of the Bladder from a man aged forty-eight, who had suffered during life from Hæmaturia. 3. Aneurysm of the first part of the Aorta, from a man who had suffered during life from a pulsating tumour in the left third intercostal space. 4. Spleen, Abdominal Glands, and Thyroid Body of a patient who had died of Hodgkin's Disease. 5. Abscess of Liver (one large and numerous small ones), probably septic, following gonorrhœa and pelvic inflammation. 6. Secondary Abscesses of Brain in the above case.

Dr. ELDER showed the parts removed by Hysterectomy, in a case of Uterine Fibroid and Hæmorrhage.

Poisoning by Syrup of Squills.—Dr. MUTCH read a paper on this subject. After a brief review of the chemical properties of squills, he proceeded to relate the symptoms produced in the four cases which had come under his observation:—Isaac B——, aged three and a half, suffered from pains in the legs, difficulty in breathing, and prostration. His face was pinched and pale, eyes sunken, lips, fingers, and nails livid,

respiration quick, and pulse irregular. He died on the same day as first visited by Dr. Mutch—i.e., Feb. 18th, 1886. The boy had suffered from whooping-cough, and had been taking a mixture composed of syrup of squills, syrup of violets, ipecacuanha wine, and oil of almonds, for about ten weeks. Ethel B——, aged five, had taken the same mixture for the same period as the foregoing, and some days subsequent to the death above mentioned complained of her legs giving way, of falling several times, and of vomiting. Her eyes were sunken, respiration and temperature normal, face pale and livid; her pulse was irregular and intermittent (one in every four beats); pupils normal. She died suddenly five days after the onset of these symptoms, on Feb. 26th. A post-mortem examination was made forty-eight hours after death, when the chief signs were found to be—fluidity of the blood, arrest of the heart's action in systole, and lividity. The two remaining cases, L. B.——, aged eight, and T. B.——, aged six and a half, presented the above symptoms in a lesser degree. Both these cases recovered. The mixture had been analysed by Dr. Trueman, who attributed the symptoms to an especially strong preparation of squills in the mixture which had been administered.

Poisoning by Sewer Air.—Dr. HAYDON WHITE read a paper on this subject, in the course of which he discussed its effects upon the human subject, instancing gastro-intestinal, nervous, anæmic, and other affections which may arise therefrom.

Gravel and Calculus.—In some notes on this subject Mr. ALFRED SCOTT related a case of severe persistent urethritis occurring in a man of twenty-five, simulating and taken for gonorrhœa, but really dependent on oxaluria rebellious to treatment, but ceasing after passage of an oxalate of lime calculus. In the course of his two years' affliction the man married, and the wife suffered from vaginitis, apparently corroborating for a time the diagnosis of specific disorder. Another case reported was that of a woman who passed small oxalic calculi at intervals of a few months, whatever diet or treatment was adopted. Almost her only relief was from chloroform, or from full doses (half a grain) of morphia during the paroxysm; Mr. Scott strongly advised copious draughts of water during this medication to obviate ill effects. He further noted how often gravel or calculus was formed in *one* kidney only. Too exclusive a diet did not answer, and he only refused such food as "turned acid"—e.g., beer, tea, cheese, pastry, and meat—when taken oftener than once daily. Dr. UITHOFF referred to nephritic and gouty cases benefited by copious draughts of hot water taken regularly two or three times a day.—Mr. EDWARDS considered diet made little or no difference. The urine of later life, containing uric acid, was often of low specific gravity from "kidney inability"—a condition benefited by strychnia.—Mr. WILLOUGHBY FURNER explained the low specific gravity of some gouty urines by the crystallising and sinking of solid constituents; he also found little effect from diet except from lessening meat, and emphasised the fact as to Hindoos being subject to calculus.—Dr. BLACK quoted cases of oxaluria in which nitrogenous, diabetic, and non-nitrogenous dieting had been successively tried without effecting any alteration in the excretion.—Dr. EWART said calculus was rare in Bengal, where rice was more consumed; but frequent in the N.W. provinces, where the heat was more intense and the skin drier: the chief food there was wheat-flour.—Dr. MACKEY considered that the drinking-water should be taken into account when judging of causation of calculus. It was noteworthy that at Bath the waters were taken at 115° F., though they did not seem so hot to the taste.—Dr. WHITTLE referred to the hepatic and neurotic origin of rheumatic and gouty disorder.

THE COVENTRY PROVIDENT DISPENSARY.—This is one of the sound and old-fashioned Provident Dispensaries which prospers, and seems to deserve to prosper. It has 16,000 members, of whom no less than 1198 joined during last year. The mortality of the members was 14·6 per 1000, while that of Coventry was 16·2 per 1000. The four medical men received respectively £324, £333 6s. 6d., £360 18s. 9d., £332 5s. 3d. Members' payments amounted to £1820 18s. 3d.; of midwifery cases, 287 were attended by midwives, and 76 by the surgeons, whose fees on this account brought up their respective receipts to £350 or over. When this is the case a rule of the dispensary requires the appointment of another surgeon. Accordingly one was appointed—Mr. Littlewood.

Notices of Books.

Regional Surgery, including Surgical Diagnosis: A Manual for the use of Students. Part III., the Abdomen and Lower Extremity. By F. A. SOUTHAM, M.A., M.B. Oxon, F.R.C.S., Assistant-Surgeon to the Manchester Royal Infirmary, Assistant-Lecturer on Surgery in the Owens College School of Medicine. London: J. and A. Churchill, 1886.—Having already noticed at some length the previous parts of Mr. Southam's work, it is only necessary to record the issue of this the final section of it. The character of the book is fully maintained in this part, the same method and style have been preserved throughout, and those who have found the earlier volumes helpful will welcome this concluding section. There is no reference to the special forms of treatment required in different regions, but brief descriptions of the affections of various parts are given, together with some tables of comparative symptoms of diseases liable to be mistaken one for the other. Mr. Southam has not attempted to make his work thoroughly exhaustive, but rather such as may be useful to the student. We do not find in this volume any mention of abscess in the sheath of the rectus abdominis muscle. And the little vascular growth met with at the umbilicus of infants is described as composed of granulation tissue. We have noticed a few other points that might be made the subject of criticism, but, as we have said, that might seem out of place in a notice of a book which is evidently not intended to be a full, but only a brief outline of Regional Surgery.

Select Extra-tropical Plants. By Baron FERD. VON MUELLER. Melbourne: J. Ferris, 1885. New Victorian Edition, revised and enlarged. 8vo, pp. 466.—This work first appeared in the form of separate contributions to the volumes of the Victorian Acclimatisation Society, with the view of promoting the introduction and distribution of useful plants. As these papers met an actual want, there soon arose a demand for copies, which led to a rearrangement and enlargement of them, and to a subsequent publication of the work in a separate form in Victoria, and afterwards in India, New South Wales, in Germany, and in the United States. The present edition is the second that has been published in Victoria. There is therefore sufficient evidence that the work is considered a most useful one by those for whom it is intended. The greater portion of the volume consists of an alphabetical list of plants eligible for industrial culture in extra-tropical countries. Under each plant is given its botanical and vernacular names, its height and character, whether tree, shrub, or herb, the climate and temperature most suitable for its cultivation, the elevation at which it grows naturally, the economic and medicinal uses of its products, and in many cases its commercial value. The last fifty pages are devoted to most useful and complete tables and indexes. One of these classifies the plants under various heads—e.g., plants yielding cork, dyes, and fodder; fibrous, insecticidal, medicinal, oil-yielding plants, and tanning and seacoast plants, &c. Another, which must be invaluable to planters who have not access to botanical works, gives the botanical synonyms commonly used; and yet another classifies the plants in groups according to the return they are likely to make to the cultivator—i.e., whether the crop will be obtainable the first, second, or third year, or only after several years. These are details which are useful to farming emigrants and intending planters. A dip into the contents of this volume will show that Baron Mueller must keep a systematic record of current literature, since his book affords the latest information concerning the uses and properties of plants. Thus the anæsthetic action of cocaine, and the uses of jaborandi and pilocarpine are mentioned. Although chiefly

intended for those engaged in agriculture, horticulture, forestry, and acclimatisation generally, and the work will probably afford the medical practitioner who may have leisure to glance through its pages some useful suggestions. As a dictionary of economic and medicinal plants it will be widely useful. One can only feel surprise that such a work should not have issued from Kew rather than from the colonies, seeing that the former is, or should be, the centre of botanical information. Australia may be congratulated on the possession of a botanist who not only has thoroughly at heart the interests of the colony in which he resides, but who is anxious to benefit the whole world by the distribution of botanical knowledge of sound practical value.

The Sale of Food and Drugs Acts, 1875 and 1879, with Notes and Cases, also Practical Observations bearing upon Legal and Chemical Questions which have arisen in the Working of the Acts. By WILLIAM JAMES BELL, Esq., B.A., LL.M., of the Inner Temple, Barrister-at-Law, and Fellow of the Chemical Society. London: Shaw and Sons. 1886.—The Anti-Adulteration Acts, with all their imperfections, have been, on the whole, very successful. The annual returns show a great improvement, and in some articles almost a cessation in regard to adulteration. But much fraud which might easily be stopped still exists, and local authorities, even when they are energetic, which unfortunately is not always the case, are still thwarted by unnecessary difficulties in their attempts to suppress the evil. Among these difficulties the interpretation of the law is foremost. It is not surprising that Acts framed after keen contention, and embodying the compromises which generally come of such contentions, are in some places obscure, or, at any rate, indefinite. No book which has hitherto appeared has afforded nearly as much help for the judicious application of the Acts as the little volume before us, which we may say at once is absolutely essential to all who are concerned in the matter. Mr. Bell has given the Acts as they stand, and against the clauses has appended notes describing cases in which they have received legal illustration, with the grounds on which the decisions have been given. Unfortunately, these decisions have not been very uniform, and many of them are merely those of magistrates, and do not carry great weight. Even the precedents created by the higher courts do not always accord with scientific sense, and perhaps the best that can be said for the present legal position is that it seems to afford a sufficient basis for a new Act. When Parliament, or if Parliament—we hardly know which conjunction to employ—finds time to attend to domestic business, such an Act will, no doubt, be passed. Meantime, Mr. Bell's book will prevent the trouble and expense of many hopeless prosecutions, and will assist many proper ones; and it has an additional value in the evidence that it supplies of the unsatisfactory state of the present law.

Report on Water-supply and Sewage-disposal. By W. F. TAYLOR, M.D. Brisbane: James C. Beal.—This report is the result of an inquiry made by Dr. Taylor into matters relating to water-supply, disposal of sewage and house refuse, and house sanitation. The inquiry was conducted on behalf of the Government of Queensland, who had under consideration a Bill for making better provision for securing and maintaining the public health, and Dr. Taylor, who was about to proceed to England, was requested to undertake this duty. The writer has certainly made excellent use of the seven months which he devoted to studying these questions, and his report shows that he has made himself well acquainted with all the important facts concerning each. A condensed, but sufficient, account is given of the different methods of conservancy, and the chief points in house sanitation are touched upon. Dr. Taylor has not discussed the applicability of one method or another specially to Brisbane or other Queensland towns; we presume this is beyond the limit of his instructions; but his visit to England will be useful in enabling the Queensland Government to frame a general law on sound principles.

Solutions of the Questions on Electricity and Magnetism set at the Intermediate Science and Preliminary Scientific Pass Examinations of the University of London, from 1860 to 1884. By F. W. LEVANDER, F.R.A.S., Assistant Master at University College School, London. Second Edition. London: Lewis. 1885.—A cram-book, but a good one of the kind. Such books cannot, we suppose, be dispensed with while examinations are what they are.

Year-book of the Scientific and Learned Societies of Great Britain and Ireland. London: C. Griffin and Co.—The first issue of the Year-book of the Societies (for 1884) contained a concise review of the history, organisation, and conditions of membership of the various societies, compiled from official sources. The present issue (the third) gives a chronicle of the scientific work done during the past year, and aims at affording an account of such work carried out in the various departments during the past year, a record of progress, and a convenient handbook of reference. It is a thoroughly useful compilation.

Analytical Records.

BYNIN (LIQUID MALT).

(ALLEN & HANBURY, LONDON.)

THIS is a highly diastatic malt extract, slightly alcoholic and of very agreeable taste. We find that at a temperature of 100° F. one part of the liquid acting for three hours will convert sixteen parts of starch into malt sugar and dextrin so completely that no blue colour is produced with iodine, so that one ounce will digest perfectly one pound of starch. This is a most satisfactory result, and, coupled with the fluidity and pleasant flavour, renders this preparation a most valuable one.

KINDER-MILCH (INFANT'S MILK).

(LOKELUND & CO., FENCHURCH-STREET.)

This is described as condensed milk with malted wheat extract, but without cane sugar. The analysis of Professor Soxhlet of Munich represents it as consisting entirely of maltose, lactose, dextrin, albumenoids, milk, fat, ash, and about 20 per cent. of water. Our own partial analysis is in agreement with this, but in the sample we examined there was a certain quantity of soluble starch. No granules were, however, visible under the microscope, so that for practical purposes the conversion is complete. The preparation is of uniform buttery consistency, and fat globules separate easily on addition of water, as they do from milk. We have, therefore, nothing but praise to bestow. The "Kinder-milch" is certainly most nutritious and easy to digest, and is an excellent substitute for mother's milk.

PRESERVED MILK, FROM THE BAVARIAN MOUNTAINS.

(LOKELUND & CO., FENCHURCH-STREET.)

A pure concentrated milk, unsweetened and without antiseptic. Following the directions on the label, we added 2½ parts of water, and obtained a milk which could not be distinguished from the ordinary produce of the dairy, and which proved on analysis to be of good quality. The analysis agreed with that performed by Professor Soxhlet of Munich, except that he found a slightly higher percentage of butter fat. Such slight variations must, however, occur from time to time. It will be seen that our opinion of this article of food is highly favourable.

SOLUBLE ESSENCE OF JAMAICA GINGER, GUARANTEED FREE FROM CAPSICUMS.

(STEVENSON & HOWELL, SOUTHWARK-STREET.)

According to our analysis and examination this is a perfect ginger essence. We have searched most carefully for the active principle of capsicum, and have not found the slightest trace. No less than 98·8 per cent. of the essence is volatilised by heat, including of course the fragrant essential oil, and of the residue only one-half is soluble in ether, so that the fixed resin in the essences only amounts to 0·6 per cent. As might be expected from its composition, the flavour of this essence is more delicate than that of the finest root.

THE LANCET.

LONDON: SATURDAY, JULY 3, 1886.

THE Parliament which has just come to such a premature termination may be remembered by the medical profession as the Parliament which passed the Medical Act of 1886. The profession had wellnigh lost faith in the power of Parliament to pass any Bill dealing thoroughly with the questions involved in any adequate scheme of medical reform. This loss of faith is not repaired by the Bill which has just become an Act, and which we print *in extenso* to-day. Judged either by what it does, or by what it leaves undone, the Medical Act is a very imperfect measure. It does not give a One Portal in each division of the kingdom; it does not equalise the severity or the cost of what should be equivalent examinations in different divisions of the kingdom; it does not secure that examinations which purport to be something above the common examinations shall be what they purport to be; it does not deal with questions of unqualified practice, or with the powers and duties of the medical bodies or the Medical Council, in regard to cases of unprofessional conduct in registered medical men; it does not give the Medical Council more efficient powers than it possessed in 1858, or reduce its size by abolishing the principle of separate representation of medical authorities in the Council; on the contrary, it abolishes the principle of *grouping* or combined representation, which we have always recommended, and which was recommended by the Royal Commission, nearly all of whose recommendations have been disregarded. This is a grave list of things not done by the new Act, which we regret to have to frame, and which greatly moderates our satisfaction with it, the more so when we consider that Parliament has no relish for Medical Bills, and will think that it has now discharged its duty on this score for many years to come.

Let us come now to things done by the Bill, and see if we can rise to a feeling of approval, if not of gratitude. Briefly, the Bill secures the following objects.

I. It enacts that after a certain day no person shall be registered under the Medical Acts who has not passed a qualifying examination in Medicine, Surgery, and Midwifery. The Act recognises that all universities acting singly may grant such treble diplomas, but that corporations must act in combination for this purpose. With the view of securing standards that shall guarantee sufficient knowledge and skill in candidates for diplomas, it is made the duty (Clause III., page 2, Subsection 2) of the Medical Council to appoint a number of inspectors to attend all or any of the qualifying examinations. This scheme may prove one of the most important in the Bill. But everything will depend on the way in which it is worked, on the number and character of the inspectors, and the instructions given to them by the Council. The Medical Council may represent to the Privy Council that the standard of proficiency of any body is not maintained, and the Privy Council may, "*if they think fit*," withdraw from the bo[illegible]ght to hold qualifying examinations. Here we ma[illegible]ssist the action of the Privy Council is often required [illegible]this Act. The frequency has been somewhat abated, in deference to our own representation, but its powers are still considerable.

II. The Act contains a very novel clause (V.), which enables the Medical Council to enter into co-operation with a corporation that has tried and failed to enter into combination with another corporation to grant qualifying diplomas. This clause is understood to contemplate and facilitate the resuscitation of the Apothecaries' Societies, or, perhaps, to put a gentle pressure on other corporations to admit them into a combination scheme.

III. The Act enlarges and modifies the constitution of the Medical Council, by giving a whole member to certain bodies that have hitherto not been represented in the Council, or only so jointly with another similar body, and by conceding for the first time direct representatives of the profession, five in number. This is the part of the measure for which the profession will feel most grateful to Sir LYON PLAYFAIR. True, the five direct members will be confronted by about twenty members sent to represent the "interests" of examining bodies or universities, to say nothing of five Crown members, who have generally been men prominently *official* in the universities or corporations. But we must be thankful for small mercies—for the five members,—thankful to Sir LYON PLAYFAIR for four, and to Dr. FOSTER for inducing him to concede another at the expense of the Crown representation. The President of the Council is to be the returning officer for the election of Direct Representatives; he is to issue his order to the Branch Council for their election not later than Nov. 15th, and they are to come into office on Jan. 1st, 1887. The direct representatives are to be chosen by registered medical practitioners in the several parts of the United Kingdom. They must themselves be registered medical practitioners. The regulations for the conduct of the election are to be made by the Privy Council. The candidates must be nominated by at least twelve registered medical practitioners. The election is to be conducted by voting papers to be issued by the Branch Council in each division. Clause IX. provides that on the occurrence of a vacancy in the chair, the President shall be chosen from the members of the Council. An important clause (X.) provides for the revision of the constitution of the Medical Council at any time by the Privy Council, on the suggestion of the Medical Council. A Body that is diminishing in importance may, under such a revision—brought about by a representation of the Medical Council to the Privy Council,—be deprived of its representative in the Council. On the other hand, a new Body, with the power of granting the treble qualification, may by the same process be admitted to representation.

Clause VI. has a rather pretentious title: "Privileges of Registered Persons." The clause, however adds nothing to the existing privileges of registered persons, and detracts in no degree from the existing and excessive liberty of unregistered persons. The Bill, in fact, deals incourageously with the question of illegal practice, and shows a tenderness to quacks, or a fear of their friends in Parliament, which is not magnanimous or for the public good.

The Second part of the Act has reference to the registration of colonial and foreign practitioners. It proposes to take powers for the recognition and registration of such degrees; but we objected to a power reserved for the Privy Council to "order" the registration of such degrees by the Medical Council, after it had refused to recognise them. (Clause XIII., Subclause II.) It is strange, and not very creditable, that the Council took no objection to this provision, which might place it in a humbling and undignified position. We expressed ourselves strongly on the subject, and the clause has been somewhat softened in tone and process; but the power still remains. Holders of Foreign Degrees, who are also registered medical practitioners, will be able to cause a description of such degrees to be added to their name in the Medical Register, provided they satisfy the Medical Council that the degrees were obtained after examination and prior to the passing of the Act.

The Third part of the Act contains miscellaneous provisions. One of these has in view default of duty by the Medical Council, in maintaining standards of examination, in appointing inspectors of examinations, or in any other way; and enacts that the Privy Council may, of their own motion, take up the neglected duty of the Council. There are also sundry provisions for the registration of qualifications in midwifery, in sanitary science, &c.

Such is the Medical Act, 1886, representing the conceptive and parturient powers of three or four Parliaments and as many Ministries. We cannot affect enthusiasm for such a piece of legislation. Possibly the system of Inspectorships may work more effectively and even more economically than the system of Visitation hitherto followed. The introduction of the Privy Council as an authority to check and control the Medical Council, if anything more than a form, is a painful proof that the Medical Council cannot be trusted to act independently. We are glad to acknowledge that, somewhat in deference to our own representations, the frequency of such introduction has been materially diminished. The most boasted feature of the Act is the requirement of the triple examination in Medicine, Surgery, and Midwifery as henceforth a condition of *qualification*. But there is now scarcely an examination in which the three branches are not already included, and the Bill adds to the cost of qualifications by requiring the combination of corporations. The concession of direct representation has been long a foregone conclusion. But nevertheless, as those who have long laboured for it, we are thankful for it, and comment in another column on some of its aspects. In fine, we accept the Act of 1886 with some satisfaction, but with a painful feeling that the evils revealed by the Royal Commission remain unremedied.

SEA-VOYAGING has in recent years greatly advanced in favour as a therapeutic agent. Few vessels now start on any of the longer voyages without one or more passengers whose chief object is health, and the few fine Australian clippers which still hold the seas against the encroachments of steam frequently reckon on their list as many as a score of invalids for a single voyage. We see overtaxed statesmen and weary brain-workers of every class resorting to yachting for the resuscitation of health; and regular announcements now appear in the press of "invalid ships" advertised to sail the summer seas, and fitted up with every requisite to secure the comfort of the weak and ailing.

There can be little doubt that this custom rests on a firm basis of reason, and is amply justified by its results. Sea air is a marvellous tonic and restorative, and nowhere can it be enjoyed to such thorough advantage as on shipboard. It appears to owe its beneficial qualities mainly to its perfect purity and entire immunity from those sources of contamination which are more or less operative everywhere on land. Pure air can be enjoyed on the desert or on the mountain top, but in its highest perfection probably on the surface of the ocean. Here all the usual sources of atmospheric pollution — such as putrefaction, combustion, and effete animal matters — are conspicuously absent. Between sea and sky sweep unrestrained the ocean winds, ready to bear far away any taint of corruption which may from any chance have been generated. How vastly important in this consideration, in view of modern scientific teaching, need hardly be pointed out. This age sees in morbid germs the "power and potency" of a vast range of diseased action, and recognises, no doubt truly, in corrupted air the nidus in which alone these germs can acquire the development necessary for their full activity. Our present knowledge all points to the conclusion that in an ideally pure atmosphere all germ-begotten disease would be an impossibility, and the aim of modern preventive medicine is not so much to destroy the sources of contagion (which is probably for ever beyond our power), but to deprive them of those necessary conditions of activity without which they are comparatively innocuous and inert.

It is unfortunate that on shipboard, while perfect purity of air always exists on deck, a very different condition too commonly prevails in the saloons and sleeping cabins. Good air being always obtainable by stepping on deck, ventilation is often insufficiently attended to; the cubic space allotted to each individual is wholly inadequate for the delicate and ailing, and in many ships the evil odours in some manner mysteriously generated are indescribably nauseous and disgusting. In this respect steamers are much more at fault than sailing vessels. Now, the healthy passenger, who goes to sea merely as a means of reaching his destination, may afford to endure with what patience he can command the foul air of an unventilated saloon or the still more noxious atmosphere of a small cabin, where four people are crowded together in a space that on land would be thought ridiculously inadequate for one; but the invalid cannot tolerate such things without putting to the hazard the major part of the advantage which he hoped to gain by braving the perils of the sea. The first and most imperative requisite, then, of the invalid ship is adequate saloon accommodation, roomy sleeping cabins, thorough ventilation by day and night, and rigorous care in checking the evolution of foul gases.

Purity is not the sole virtue of sea air. Its remarkable equability is hardly less important, especially for consumptive invalids. Sudden changes of temperature are practically unknown upon the ocean, and the diurnal range of the thermometer there attains a minimum. Hence sailors enjoy a comparative immunity from diseases traceable to exposure, catarrhs are rare among all classes on ship-

board, and in tropical and subtropical regions passengers frequently sleep upon deck without injury. This equability is of the first importance to all sufferers from respiratory disease, who are prominent amongst the number of those who derive signal benefit from the sea voyage. The barometric range at sea exhibits for the most part great equability, and the changes of pressure are more regular and uniform than upon land. This is probably not without an important influence upon the organism. The impregnation of sea air with traces of bromine and iodine has also no doubt its part in the general therapeutic influence exerted.

One of the first effects of the ocean voyage, after the usual initial inconvenience of sea-sickness has been successfully surmounted, is a great stimulation of the appetite. Hence the choice and regulation of food on shipboard are matters of vital importance; but too often the dietary, even on the best ships, is arranged on a purely routine system, with little regard to change of climate or to the special needs of the invalid. In some ships roast beef and plum pudding greet the passenger with unfailing regularity even in the sultriest region of the torrid zone. Meat is abundantly supplied and liberally partaken of as often as three times daily, although the heat of the atmosphere and the scanty amount of physical exercise usually practised on shipboard should suggest even to the most thoughtless some moderation in the consumption of animal food. From such indiscretions spring the dyspeptic troubles which in so many cases constitute a serious set-off to the great benefits so usually derived from the ocean voyage. The dietetic principles which should prevail on shipboard are sufficiently obvious. In the higher latitudes, if the passenger take a reasonable amount of exercise, there is no reason why he should not eat and drink as has been his usual habit on land, provided he keep in view that at sea there is increase of appetite with decrease of activity. As the equator is approached, butcher's meat should give place to poultry, farinaceous foods should have the preference over the heavier articles of diet, fat in the form of such dishes as suet puddings should temporarily disappear from the daily bills of fare, and vegetables should be supplied as liberally as the exigencies of ocean voyaging permit. As regards drinks, there is nothing so grateful or so generally useful in the very hot latitudes as the simple juice of the lemon. Alcohol is injurious, and all hot drinks are at such times usually in a large measure voluntarily abandoned. As the vessel runs into cooler latitudes, the usual dietetic practices of the average Englishman may be gradually resumed.

With such simple and obvious precautions, the ocean voyage may take its place as one of our most valuable restoratives. It is applicable to most cases of debility, from whatever cause arising, provided there be neither great prostration nor marked irritability; it is especially valuable in incipient phthisis and in hereditary tendency to scrofula, and it finds one of its most useful applications in cases of retarded convalescence from surgical operations or acute disease.

THE interesting observations by Dr. COATS, which are to be found in another column, go far to determine a question that has exercised the minds of students of auscultation throughout the seventy years that this method of physical exa[illegible] has been practised. What is the cause of the pul[illegible]reath sounds? Are they, as LAENNEC conjectured, the mere transit of air through the bronchial passages? Are they produced by the actual unfolding of the lung on its expansion, and the outflow of air from the lobules with expiration? Or are they extra-pulmonary in origin in whole or in part? Some of these conjectures are purely fanciful, and, since the universal adoption of the *veine fluide* theory, are quite untenable; but a clearly satisfactory solution is still complicated by the readiness with which sound waves are conducted through the media that we find in the respiratory apparatus. The doctrine that the respiratory murmur is wholly extra-pulmonary, and consists really in the sounds created by the passage of air through the glottis, modified by the peculiar texture of the lung through which they are conducted, has received some countenance both abroad and in this country. But this teaching was fairly disproved by the experiments of BOUDET and CHAUVEAU, and has practically received a *coup de grâce* at the hands of Dr. COATS, whose observations are the more important because they were conducted upon the human subject. By means of the apparatus which had been substituted for the larynx, after extirpation of that organ, Dr. COATS was enabled to test the auscultatory phenomena when the glottic aperture was absent; and he was further able to modify the conditions of his experiments and thereby to arrive at juster conclusions. Thus, in the first place, where breathing was only carried on through the tracheal tube, the loud expiratory sound produced at the open mouth of the tube could be heard to be freely conducted all over the chest in the line of the tracheo-bronchial channels, but to be obviously damped by the pulmonary parenchyma. Since the conditions did not allow of a *veine fluide* being produced at the open mouth of the tracheal tube during inspiration, there was only a very feeble inspiratory murmur audible over the trachea, which became more intense as the lungs were reached, eventually assuming the characteristic vesicular character. This observation by itself is of much value, as showing not only the readiness with which the trachea and bronchi conduct an expiratory murmur, but that the pulmonary inspiratory bruit is probably solely produced at the infundibula. Again, by causing the patient to breathe through the narrower pharyngeal tube, the actual conditions of the glottis were simulated, with the result corresponding to the signs observed in the natural body. Lastly, the experiment was further varied by narrowing the tracheal tube, and thus again reproducing a "glottis," with the consequent generation of sound both during inspiration and expiration, the inspiratory murmur much predominating over the expiratory, in the direction of the current. The conclusion arrived at by Dr. COATS was, it will be observed, verified by a committee composed of Drs. GAIRDNER, NEWMAN, and STEVEN, and it amounts to an emphatic denial that the glottis has anything to do with the production of the normal vesicular murmur. Thus, as so often happens, do we find a theory which had been accepted by one generation overturned by another; and, small as the point in question may be, it is at least instructive for those who may pursue the path of inquiry that still remains open. We have now before us two sources of distinct

respiratory sounds — the laryngeal and the tracheal. The limits of the former have been clearly defined; the precise mechanism of the latter remains matter of conjecture. By excluding laryngeal sounds from any share in the production of the vesicular bruits, we are driven to seek in the structure and mechanism of the pulmonary tissue itself for the conditions of these latter. But no one can assert that we know precisely in what way these sounds are produced. We find them modified in disease and variously altered with the varying textural changes in the lung, but a demonstration of their mode of production which shall also harmonise with these changes is still to be desired.

IF Europe is again this year to be visited with cholera in an epidemic form, it will probably be during this month that the diffusion will take place from the centres in which the disease has manifested itself since the cessation of the epidemic prevalence of 1885. It may therefore be convenient now to give a summary of the movements of cholera in Europe during the present year, in so far as official and other intelligence has been received in this country.

In France the disease has been almost entirely confined to the north-west, where the neighbourhoods of Brest and Quimper appear to have suffered in consequence of importation from the south. In several localities the disease was a continuance of that which prevailed before the close of 1885, and in others the extension was a new one. Early in January, Concarneau, Douarnez, Audierne, and Brest were attacked, and by the middle of March the cholera deaths which had taken place in those localities were 13, 27, 4, and 35 respectively. A later occurrence of the disease took place at Tréboul, where a large number of cases were announced to exist; but some exaggeration probably took place, for the mortality was limited to six cases. Since the middle of April no cholera intelligence has been received from France.

In Spain, cholera has during 1886 been altogether limited to the extreme south, in so far as any intelligence has been allowed to reach this country. Early in January the disease caused 11 deaths at Algeciras; about the same date 8 fatal attacks took place in the province of Malaga; and later on a summary account of what had taken place at Tarifa was received, from which it appeared that up to the end of the first week in March 63 deaths had been registered there. No further news has since been received on the subject.

Italy has been much more severely affected since the close of last year than either France or Spain. The first cholera deaths this year were announced from Brindisi early in April last, and the disease extended into May, by the end of which month 31 deaths had occurred. A cessation of fatal attacks then ensued, but after the middle of June the disease again began to cause a daily fatality. Up to the end of the month over 60 deaths took place, making a total of between 90 and 100 deaths at Brindisi. When the disease first appeared at Brindisi, 2 deaths also occurred in the neighbouring town of Monopoli. The disease further extended into the province of Brindisi, where fatal attacks took place during May, and then, after a cessation, recurred and were maintained up to the end of June, some 70 deaths in all being registered. Soon after this the disease was found to prevail in the neighbouring port town of Bari, where fatal attacks were first noted about the middle of May, and where, with but occasional intervals, they have been maintained into the third week of June. In May 70 deaths took place there, and to these must be added some 35 during the month of June, or over 110 in all.

But before Bari was infected intelligence came as to the reappearance of the disease in the north. During the winter months cholera occurrences had been announced in the districts between Venice and Trieste, and early in May isolated deaths occurred again in Venice. Steadily the disease made progress, and by the end of the month over 150 fatal attacks had occurred there, the largest fatality being reached towards the end of the month. With the onset of June the fatality was maintained, but since the middle of the month there has been a steady tendency to decrease until the fatal cases have been reduced to about one a day. During June over 210 deaths occurred, making in all a fatality exceeding 360. During the same period of two months, over 300 cholera deaths took place in other localities in the province of Venice. Setting aside a few isolated attacks due to importation, no further outbreak of importance took place until Codigoro, a port town to the south of Venice, on the estuary of the Po, was announced to be infected during the fourth week of June, and where 41 deaths were stated to have taken place. With this single exception, cholera in Italy is less fatal than it was about a month ago, but nearly 950 deaths have occurred in that kingdom this year, and the tendency to abatement, with subsequent recurrences on a wide scale, is too important an element in the natural history of cholera diffusions to give much hope of a real decline in the prevalence at this time of the year. July and August are essentially the cholera months for Europe, and these months we still have to face.

THE enactment of direct representation of the profession in the Medical Council is a historical fact to be considered. It is painful to remember that cliquism has always existed in the profession. It used once to dominate nearly all hospital appointments, and he would be a bold man now who would deny that it sometimes yet tells in elections that should be purely impartial. We shall not here dwell on the past. At length, against Governments, and against the whole tone and letter of the Medical Council, the Legislature has recognised the reasonableness of giving to medical men, whose fees maintain the Medical Council, whose education is supposed to be regulated by it, whose names may be erased from the Register by it, a representation has been conceded. The representation is indeed inadequate; its proportion to that of the representation of officialism and "interests" will be that of one to five or six. But, such as it is, it is at last a fact. Let us hope that other lesser authorities—the councils of our colleges, &c.—will take a lesson and show a little more respect to the claims of the rank and file of the profession. It is premature to discuss the persons who should be entrusted with this honourable duty. It is more to the point at present to consider the nature of the duties they will be called upon to discharge, and the general principle which should guide the profession in selecting its representatives. There are many reasons

why this representation should be begun well, both as regards the method of conducting the election and the selection of candidates.

First, as to the method of election. Our readers will see by another article, and by the Act itself, which we publish to-day, that the election is by voting-papers. Each member of the profession in November will receive from the Branch Council of the division of the kingdom in which he lives a voting-paper, in which he will be able to vote for as many direct representatives as are to be elected for the division. It is of the greatest possible moment that this election should not degenerate into a contest like that for a Member of Parliament. Canvassing in the ordinary sense of the word should be discouraged. The number of candidates should not be too great, and when nominated, as they require to be, by at least twelve members of the profession, they should leave their election very much to the unbiased vote of the members of the profession.

The direct representatives of the profession will have it in their power, we trust, from time to time to be of much service, primarily to the public, and secondarily to the profession. But they will have to keep within the four corners of the Medical Acts, and they will best discharge their own duties to their constituents by strictly observing the limits of the law under which they act. This law may ultimately have to be amended, and for once the representatives of the profession will have the vantage-ground of the Council for urging the necessary amendments. But for the present all they can do will have to be done under the present Acts. Their duties will have reference chiefly to—(1) the regulation of the subjects of preliminary and medical education; (2) the accuracy of the Medical Register; (3) the perfection of the Pharmacopœia; (4) the fairness and efficiency of the examinations of the various medical authorities; (5) the case of members of the profession lying under imputation of unprofessional or criminal conduct. These are all weighty subjects. They have hitherto been treated by the Medical Council too much as if they were the peculiar care of the medical schools and examining authorities. In future we may hope to have practical contributions to their settlement by members of the profession who view these questions from the standpoint of general practice. Whoever the gentlemen may be to be chosen to represent the profession, it seems desirable that they should be chosen chiefly from the ranks of general practice. Members of the consultant and the official section of the profession already practically make up the Council. It is time that the ranks of general practice should be represented.

ON the occasion of the celebration of the jubilee of the British Medical Benevolent Fund, Sir James Paget, who has taken immense trouble to render the gathering a success, will be supported by Sir W. Jenner, Sir A. Clark, Sir J. Lister, Sir Prescott Hewett, Sir J. Fayrer, Sir Dyce Duckworth, Dr. Habershon, Mr. G. Pollock, Dr. Clifford Allbutt (Leeds), Mr. Cadge (Norwich), and Mr. Lund (Manchester). Cardinal Manning and the Dean of Gloucester will be among the visitors. The benefits conferred by this fund upon the members of the profession have been but recently stated in a forcible manner by Dr. Broadbent; and we sincerely hope that, despite the dissolution of Parliament and the consequent turmoil of a general election, the jubilee celebration will earn the title of "a great success."

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF LONDON.

MR. MAGNUS'S scheme for reconstituting the University passed through Convocation on Tuesday last without any substantial modification, except the omission of the clause giving power to the Senate to confer honorary degrees. Convocation, though not without protest on the part of many members, has pledged itself to the adoption of fundamental changes, bringing the authorities into closer contact with the teachers. Certain educational institutions having one, or more than one, faculty of university rank are to be admitted as Constituent Colleges; a Council of Education, composed of representatives of Convocation, of Constituent Colleges, and of the Examiners of the University, is to be formed; and the Senate is to be modified by the introduction of direct representatives from University and King's Colleges, the Royal Society, the Colleges of Physicians and Surgeons, the Council of Legal Education, and the Incorporated Law Society. By consenting to such a scheme as a basis of conference with the Senate, Convocation, after summarily rejecting Lord Justice Fry's proposals, has, under the guidance of Mr. Magnus, practically acceded to every demand which has been made by those who support the Teaching University scheme. The power of the teachers becomes a substantial factor in the University, instead of being consistently ignored or resisted. Moreover, the institution of an intermediate body between the Senate and Convocation, no matter whether it be called a Council of Education or a Board of Studies, is a distinct gain to the teaching element, and by it many salutary changes in the examinations and regulations are sure to be initiated. The change in the vote of Convocation on Tuesday from that given in November last shows how little value can be attached to the opinion of such a fluctuating body, and it was apparent at the meeting that most of its interest in the reform had dwindled away. About seventy members only were present, and at no time were there a dozen medical graduates at the meeting. Since the formulating of Lord Justice Fry's scheme, the chief reformers on the teaching line—such as Sir Edward Fry himself, Mr. H. Matthews, and Dr. Pye-Smith—have been appointed on the Senate, and the vote for Dr. Wilks will add another distinguished Fellow on the same side. The centre of interest has shifted now from Convocation to the higher body.

THE CROONIAN TRUST.

THE increased income from this Trust, which has caused so much perplexity to the Fellows of the Royal College of Physicians, was finally disposed of at the meeting on the 29th ult. The subject had been before the College at several previous meetings; the Council had submitted two schemes, and several eminent Fellows had proposed amendments, so that only after a protracted discussion could the final voting be taken. We venture to think that the decision not to tie the hands of the College authorities any tighter than is absolutely necessary for the satisfaction of the legal conditions of the Trust is a very wise one. The very fact that it is now proposed to alter Lady Sadlier's bequest from the prosecution of the study of Anatomy, to which she devoted it, to the wider area of "Anatomy, Physiology, and Pathology, with a view to the prevention, control, and cure of diseases," shows plainly that what is considered the most urgent need in the progress of medical science in one generation is in an entirely different position in the next. For this reason especially, we are pleased to see that the exclusive devotion of the

Trust to the prosecution of Therapeutic Inquiry was rejected. Therapeutics now comes under the head of [illegible] as a branch of physiology in respect to the control and cure of disease just as physiological chemistry does, but it has not a primary claim on the attention of the lecturers and investigators who will be appointed by the College on this foundation.

THE INTERNATIONAL MEDICAL CONGRESS.

IN spite of differences on code questions, territorial questions, &c., in the profession of the States, it is evident that there is to be an International Medical Congress in Washington. This being so, it ought to be the endeavour of all parties to make it a complete success, worthy of the nation that is to act as host, and the nations that are to be received as guests. Much has yet to be done in this way. Undoubtedly some of the best known leaders in the States are still standing aloof. We should be glad to hear that they were abandoning that attitude and kindly taking to arrangements which are the best compromise that can be made in the circumstances. Dr. Nathan S. Davis, of Chicago, is to be president in place of the lamented Dr. Flint, and the preliminary organisation of the Congress is in a forward state. Dr. Davis is a veteran in the profession, and much respected, though less known in Europe than some of his *confrères*. A correspondent, who is well informed, thinks the arrangements are now on the high road to success. He says that efforts will be made greatly to reduce the cost of tickets for the voyage and for visiting all parts of the country, and that arrangements in Washington are likely to be satisfactory. Another valued correspondent, writing from New York, says: "The Congress is to be, and it is to be a success. The troubles are healing over, and before the Congress meets I think all difficulties will be, to all intents and purposes, settled."

ELECTION MORTALITY.

THERE is a profound and, as yet at least, inscrutable mystery about the operation of those laws of nature which determine the rate of mortality. This is equally true of the civilised and of the uncivilised portions of the human race, scattered over the whole face of the earth, under the most diverse conditions. If at any time it seem likely that the rate of mortality will fall below the normal point, some special "visitation," as it is called, occurs, and the balance of life and death is readjusted. History supplies conclusive evidence of the truth of this general proposition. It is nevertheless, startling to be confronted with the facts about mortality, and perhaps no others are more striking than those which show that every great commotion, whether of mind or muscle, produces its crop of deaths due to the disturbance set up or the effects following upon it. A general election forms no exception to the working of this law. That of 1886, following as it does close upon the election of 1885, is only too likely to be fruitful in this terrible respect. Already there have been cases of death occurring suddenly as the result of exhaustion by nerve excitement, and by disease either contracted or aggravated in the course of the proceedings connected with the election. It is more than probable we shall have to deplore further losses. There is something in this wholly apart from the mere incidence of mortality on the proportion of persons occupied with the political crisis. We know how—resting for its basis of fact on the incidence of the death-rate proportionally—there has grown up a strongly-rooted belief that of thirteen persons dining together on any single occasion one will die before the end of the twelve months following. The truth is, that of any large number more than one is likely to die, and so on. The same law of proportional incidence of the average mortality, of course, applies to classes or sections of the community generally; and it is inevitable that of the thousands actively engaged in the election now in progress, a notable number must, in the nature of things, die before it is completed. Outside this, there is the fact that the perturbation into which minds and bodies are thrown by the exceptional business of the crisis has what must be regarded as its own proper fatality. In short, a definite number of persons will be *killed* by the election. With a view to minimise that number as far as possible, it would be well if the fact last mentioned could be more generally understood. There is the making of death in the extreme mental excitement stirred by the election, in the exhaustion of brain and muscle which it must cause, and in the exposure to heat or cold which cannot be avoided. It is easy to make light of these matters, but that does not in the least degree diminish their importance. Far more reasonable would it be to recognise the risks entailed by exceptional activity or exposure, or both, and to meet the dangers which actually exist with rational measures of precaution. Those who are conscious of weakly organisms would be simply prudent to avoid too severe demands upon their strength and vitality; and those who, while thinking themselves to be sound and strong in mind and body, are conscious of being what is pleasantly described as "excitable," should understand that irritability seldom exists without weakness, although the seeming energy of excitable persons is apt to mask their want of real power and stability. It is better to be a little niggardly in the output of strength than to die of exhaustion, and discretion is certainly the better part of valour in respect to the running of risks by undue exertion or exposure. It is no part of our business to suggest or even countenance the neglect of duty in a social or political crisis; but there are always two ways of doing a thing, and those who must need mingle in the fray of a particularly hot election contest will find the coolest and the most self-controlled way of doing what has to be done at the behest of duty the best.

REMARKABLE ACCIDENT WHILE TAPPING A HYDROCELE.

A RARE and remarkable accident during the ordinary operation of tapping a hydrocele is reported from Bordeaux. The patient was a healthy peasant of forty-four years of age, who had never suffered from any venereal affection. The hydrocele, which was on the right side, had been in existence some two years, and had followed an accidental blow. As it continued to increase in size, he sought advice, and was admitted into M. André Boursier's clinic. When the trocar was introduced, about 125 grammes of straw-coloured fluid came away. M. Loumeau, who performed the operation in M. Boursier's presence, then, having satisfied himself that the extremity of the cannula was free in the cavity of the tunica vaginalis, proceeded to inject gently sixty grammes of a mixture of tincture of iodine with twice its volume of water. All at once the patient complained of severe pain in the cord and the loins, with cramp in the right forearm. The ulnar border of the right hand then became flexed, the ring and small fingers being completely flexed, while the index and middle fingers, though extended as far as the second and third phalanges were concerned, were flexed at their metacarpo-phalangeal articulations. The thumb also was flexed and brought near the fingers. Exactly the same position was shortly afterwards assumed by the left hand. There were no convulsions or syncope. After a few minutes the "ulnar *griffe*" began to relax, and the index and middle fingers became flexed completely on the hand, which itself became strongly flexed on the forearm. All the muscles on the front of the forearm became hard and contracted. The palmar fascia was strongly retracted, and

the palmaris brevis quite tense. On both sides the ulnar affection had given place to contraction of the muscles supplied by the median nerve. The patient was unable to articulate a sound, his tongue hanging loosely in the buccal cavity. The muscles supplied by the hypoglossal nerve were also contracted, but for a short time only. The forearms were shampooed, and after nearly an hour the muscles relaxed. The patient recovered completely, and left the hospital after a few days. M. Loumeau has been unable to find an example of this kind in medical literature; but M. Desplats of Lille published a paper on pleural eclampsia last year in the *Semaine Médicale*, in which he refers accidents connected with pleural operations to four categories: (1) Toxic action of the liquid injected, (2) true epilepsy, (3) uræmia, (4) reflex action. The author surmises that the accident was due to reflex irritation of the nerves of the serous membrane by the liquid injected. The testicle, it may be remarked, was in no way injured. Whatever explanation may be offered, the fact remains, which is itself sufficiently extraordinary, of a healthy peasant man of middle age being thrown into a state of severe nervous spasm by the performance of a very simple and very common surgical proceeding.

OATHS IN COURTS OF LAW.

IT will be remembered that several letters recently appeared in these columns under the heading "Kissing the Book." They arose from the circumstance that a medical witness, when giving evidence in the Divorce Court, objected to kiss the book presented to him, on the grounds that, as the two previous witnesses were common prostitutes, he might incur a risk of infection. Simultaneously, several medical witnesses in different parts of the country made each a similar objection, the difficulty in each case being eventually got over by the witness being permitted to kiss the open book. Mr. John Patterson, J.P., of Liverpool, has recently addressed a letter to one of the local daily papers, in which he calls attention to an Act of Parliament which is still in force, and which runs as follows:—

"1 and 2 Victoria, c. 105, 14th August, 1838.—Be it declared and enacted—That in all cases in which an oath may lawfully be and shall have been administered to any person, either as a juryman or a witness or a deponent in any proceeding, civil or criminal, in any court of law or equity in the United Kingdom, or on appointment to any office, employment, or on any occasion whatever, such person is bound by the oath administered, *provided the same shall have been administered in such form and with such ceremonies as such person may declare to be binding*; and every such person, in case of wilful false swearing, may be convicted of the crime of perjury in the same manner as if the oath had been administered in the form and with the ceremonies most commonly adopted."

Mr. Patterson contends from this that any Presbyterians may claim to be sworn as their co-religionists in Scotland and Ireland are, *with uplifted hand*. We have taken some pains to ascertain the law upon this point, and find that not only is this true, but also that any native of Scotland or other country where the oath is administered with uplifted hand may claim to be sworn in a similar manner. And, moreover, any person who declares that that is the method of taking the oath which he considers binding may claim to be so sworn, be his or her nationality or religion what it may. All that is required by the Court is that an oath shall be taken before it. It will thus be seen that all those witnesses who object to kissing the book can avoid doing so, provided they declare that by holding up the right hand while the words of the oath are repeated they consider themselves duly sworn. Whether this may lead to the universal adoption of the Scotch oath remains to be seen, but there can be no second opinion as to its being preferable to the present [illegible] adopted in England. Even if the risk of infection [illegible] remote, the successive handling and kissing of the [illegible] book by a number of witnesses is, to say the very least, an uncleanly practice. Should any objection be taken by the Court to a wholesale preference for the uplifted hand, perhaps each witness will be permitted to bring his own Testament.

THE INDO-COLONIAL EXHIBITION AND EMIGRATION.

THE opening of an Emigration Inquiry Office in the Exhibition at South Kensington will for several reasons be regarded as an important step in the right direction. As to its economic significance there is little need for us to speak, though its salutary influence in helping to deplete an overcharged labour-market is obvious. Another aspect of emigration should not be forgotten. There are many in humble life who are and may long continue to be physically sound, but who are constitutionally unsuited to our uncertain climate. Everyone is familiar with the lymphatic type so common in Teutonic races. Capable of much muscular exertion, but dependent in a marked degree upon wholesome conditions, it suffers unduly by the crowded and laborious life of great cities. Emigration to the Southern Colonies offers, to any who inherit this predisposition, the opportunity of labour out of doors in an equable climate, and in that the best assurance of healthy development with a maximum of usefulness in time to come. For working men generally, indeed, if they be healthy, active, and sober, the chances, both vital and social, are often more favourable in wider Britain than at home, more favourable in point of daily bread, and, for the enterprising, of advancement. At the same time, all will admit that an emigrant rush is by no means desirable either for the emigrants or the country they leave behind. Fortunately it is not likely to occur. Of our unemployed but able population, particularly in the towns, we may still say there is enough and to spare.

ERYTHEMA AS A SPECIFIC DISEASE.

THE simplification of an overburdened terminology and the reduction of numerous lesions under one common head is as important a process in the advance of medical science as the converse operation; and in no department can this be more satisfactory than in that of diseases of the skin, where the terms descriptive of morbid states are excessive and not always used in the same sense. The number of species which corresponded to the genus erythema was formerly very large. An important advance was, however, made by Hebra when he united them under the term Erythema polymorphous, thus dispensing with such species as E. papulatum, circinatum, nodosum, &c., which are only used for purposes of description. But a further simplification of this group is arrived at by M. Villemin, who read a paper at the *séance* of the Academy of Medicine on May 18th, in which he combated the very prevalent idea that erythema was nothing more than a local disease of the skin, and proposed that in future we regard it as a specific disease, of which the skin lesion bears a part similar to that played by the rash in scarlatina. This is not altogether a new idea. Erythema has been regarded as connected with rheumatism or as one of the manifestations of the rheumatic diathesis; some observers have thought that the joint pains which so often accompany the disease are secondary to it, in a similar way to the joint affections which occur during the course of scarlatina. But M. Villemin regards the pains in the aponeuroses and the swelling in the joints as manifestations of one disease, of which the cutaneous eruption is also another sign. His chief reason for coming to this conclusion is that the various manifestations all yield in a marvellously rapid manner to

the action of one drug—viz., iodide of potassium—which tends to prove that they all have a common origin. The effect of this drug is surprising from its rapidity; even in doses of thirty grains, the fever, pain, and rash are held in check in the first twenty-four or forty-eight hours; while in three or four days there is no trace of the disease, though, as may be supposed, a slightly longer time is required to allow of the absorption of any liquid which has been extravasated into the skin. The general truth of this view will no doubt be admitted, but many may object to the method. Because several diseases are benefited by the same drug, it in no way follows that they have a common origin.

REPEATED VACCINATIONS IN THE INCUBATION STAGE OF SMALL-POX.

A RUSSIAN medical student, M. Gubert, recently performed a series of experiments with calf vaccine, chiefly making use of dogs as subjects for the purpose of deciding whether there is any use in vaccinating persons (1) who have already been infected by small-pox, (2) who are in the incubation stage, or (3) in whom the disease may have actually begun to manifest itself. This question, he says, has generally been decided in the negative, on the ground that insusceptibility to small-pox is only obtained thirteen or fourteen days after vaccination—that is, after a period at least equal to that of the incubation stage. Having somewhat modified the method of vaccinating, M. Gubert, who describes his experiments in the *Zemskaya Meditsina*, was able to obtain vaccine vesicles in a shorter time than usual. By repeating the vaccination on three successive days he was able to produce mature vesicles in four or five days. This rapid saturation of the organism with the vaccine virus enabled M. Gubert to arrest the development of the disease in twenty-seven persons, in whom, he states, he was quite certain that the small-pox was incubating, while in twelve others the disease was so modified as to be considered only varioloid. The vaccination was performed in some cases when the temperature had already reached 40° C. It should be remarked that all the experiments were carried out with calf lymph, so that we are as yet without information as to whether humanised vaccine could be made to "saturate the organism" sufficiently to produce mature vesicles in four or five days. At all events, M. Gubert's observations are interesting, and worthy of repetition by other practitioners.

TEA-DRINKERS' DISEASES.

IT is not a little curious that the diseases arising from the wrong use of tea should be met with in greater frequency in countries foreign to its growth. It might have been supposed that where production went on there would be found those evils that attend the consumption of tea in their greatest extent; but such does not appear to be the case. The diseases due to tea are well known to doctors, but the public seem to be strangely indifferent to the teachings of their medical advisers in these matters. Recently in France M. Eloy has reminded medical men how vast is the number of diseases owning an allegiance to the dominion of Queen Tea. The list of headings in M. Eloy's paper is well calculated to arouse attention, and, we hope, to lead to some abatement of this widespread disorder. America and England are the two countries that are afflicted most with the maladies arising from the excessive consumption of tea. Individuals may suffer in a variety of ways. It is customary to speak of acute, subacute, and chronic "theism"—a form that has no connexion with theological matters. It is possible to be a "theic" by profession or a "theic" by passion. The predominance of nervous symptoms is a characteristic of theism; general excitation of the functions of the nervous system may be observed; or the weakness may be noted more especially in the brain as distinguished from the spinal cord. Perversion of the sense of hearing is not at all an uncommon symptom—patients hearing voices that have no real or objective existence. The irritability that overtakes women so frequently may sometimes be clearly traced to an excessive indulgence in afternoon tea. It is a mistake to suppose that it is the poor sempstress who is the chief sufferer from theism. No doubt the tannin which tea that has been standing long contains does a great amount of mischief, but the derangement that it causes hardly belongs to that class of diseases with which we are at present concerned. Rather does theism belong to that genus of disease in which morphinism, caffeism, and vanillism are found. The habit of tea-drinking is one that grows on its victims like the similar ones of opium or alcohol. Taken in strict moderation, and with due precautions in the mode of preparation, tea is, like alcohol, a valuable stimulant; in its abuse there is also a certain analogy. There is hardly a morbid symptom which may not be traceable to tea as its cause. This is a fact that general practitioners often use to their own satisfaction and to their patient's advantage, if it happen to be that kind of patient who does not object to make some sacrifice in order to be rid of troubles.

AMALGAMATION OF THE PARKES MUSEUM AND SANITARY INSTITUTE.

THE definite amalgamation of these two institutions, which are both intent upon very similar work and which already occupy the same premises, has been for some time debated by the councils of both Societies. The formal assent of the members of the Sanitary Institute has already been obtained, and on the 23rd ult. an extraordinary general meeting of the members of the Parkes Museum was held for the purpose of ascertaining the views of the members on this important question. Sir Robert Rawlinson, the senior vice-president, was called to the chair, and among those present were Sir Thomas Crawford, Inspector-General Lawson, Mr. F. D. Mocatta, Captain Douglas Galton, Professor de Chaumont, Professor Corfield, Mr. Rogers Field, Mr. T. Twining, Dr. Steele, Mr. Berkeley Hill, Dr. Poore, and Dr. Parkes. It is satisfactory to state that the proceedings were characterised by an absolute unanimity of opinion, and a series of resolutions were passed, to the effect that the Parkes Museum is willing to amalgamate with the Sanitary Institute. A special committee, composed of members of the two bodies, will be appointed for arranging the details of amalgamation, and application will be made to Government to grant a Charter to the new Society. Both Societies have been in existence for ten years, and each has made steady progress in the work which it was established to carry out, and each has grown steadily in public estimation. Union is strength, and the new body must prove a very strong Society, and, looking to the position and eminence of many of the members, one calculated to have great influence with the public in guiding it in sanitary matters. There ought to be no difficulty in getting the required Charter, and certainly a thoroughly well established Society which shall serve as a rallying ground for the rapidly increasing number of persons interested professionally in sanitary science is very much wanted. The last work accomplished by the Parkes Museum has been very successful. This was a course of lectures given by a number of eminent sanitarians, and intended specially for the benefit of sanitary inspectors. Although the notice given was short, no less than sixty-four gentlemen entered for and attended this course of lectures, and the result of the examinations lately held by the Sanitary Institute (at which there were fewer failures than at any previous

examination) shows that the lectures were of solid benefit to those who attended. We understand that a second course is to be given. The arrangement of the library is proceeding satisfactorily, and all the books have now been catalogued by Mr. Taylor. The numerous pamphlets are in course of classification. The library now comprises about 6000 volumes, and it is to be hoped that the medical officers of health throughout the country will not forget to keep this central sanitary library well supplied with their annual reports and similar publications.

THE VOLUNTEER MEDICAL SERVICE.

THERE has been recently raised a considerable interest in the development of the medical department of the Volunteer army. Much has been done in London and in other populous centres; even in country parts the movement has attained large proportions. An instance of this occurred at Redcar on Saturday last, when the 2nd Volunteer Battalion of the Yorkshire Regiment was inspected after a week under canvas. This battalion, which is 600 strong, is largely recruited from the rural districts, although the headquarters are at Scarborough. The medical department consists of three surgeons and forty-one non-commissioned officers and men, most of whom wear on their right arm the Red Cross brassard, received after examination. The surgeon in command is Dr. J. W. Taylor of Scarborough, to whose zeal and intelligence the detachment owes its development and efficiency. To make up the full strength of a bearer company (sixty-four officers and men), we understand recruits are only waiting to be enrolled. So far as we know, this is the first bearer company that has been actually formed in the north of England, although it has not yet received official recognition. The bearers marched past as a company with their officers in rear of the battalion, and afterwards took part in what is known as "the attack." By permission of the colonel in command several men were permitted to fall out and feign injuries received in action. A large number of persons assembled at the collecting station, to which the "wounded" were carried, and great interest was displayed during the unloading of the stretchers. Colonel Barratt, the inspecting officer, also rode up to see the wounded cared for, and afterwards inspected the whole bearer company, and saw them execute the stretcher drill and other movements. He also presented certificates of proficiency to those bearers who had passed the examination since the last inspection. The equipment of the company consists of ten stretchers (McLure's pattern), ten water-bottles, a dressing haversack, and a field companion. The surgeons also carry small flags for signalling purposes. We commend this example of efficiency to volunteer surgeons in other places than North Yorkshire.

HEALTH OF PRESTON.

THE borough of Preston is now suffering from a severe epidemic of measles, which caused no fewer than 86 deaths in the six weeks ending last Saturday, equal to an annual rate of 7·2 per 1000 of the estimated population. The epidemic commenced in February, since which 116 deaths from the disease have been registered within the borough. This fatality is the more noteworthy since epidemics of measles prevailed in this town in 1882 and 1881, causing 125 and 61 deaths respectively. In connexion with the high death-rate from all causes that has prevailed in recent years, it is impossible not to view this exceptional mortality from measles as evidence of unsatisfactory sanitary condition. Preston was added to the list of large towns dealt with by the Registrar-General in his Weekly Return at the beginning of the year 1882, and it appears that the mean annual death-rate in the borough in the four years 1882-5 was 2[illegible]1000, which was higher than the mean rate in the s[illegible]eriod in any other of the twenty-eight large towns, [illegible]exceeded the average rate in those towns by no less than 5·4 per 1000. In other words, the mortality in Preston during those four years exceeded the mean mortality in the twenty-eight towns (including Preston) by fully 25 per cent., signifying that in equal numbers living there were 5 deaths in Preston to every 4 in the twenty-eight towns. The excess of mortality among infants in Preston was proportionally greater than the mortality at all ages. Infant mortality, measured by the proportion of deaths under one year to registered births, averaged 214 per 1000, against 160 in the twenty-eight towns, showing an excess equal to 34 per cent., or more than a third. Summer-diarrhœa mortality in Preston was more than twice as great, and "fever" mortality (principally enteric) nearly twice as great, as the mean mortality in the twenty-eight towns. It should be stated that the present population of Preston is locally considered to be under-estimated, but even should this be to some extent the case, it would not in any way affect the excess of infant mortality measured by the proportion of deaths of infants to registered births, and the marked decline in the recorded birth-rate of the borough since 1881, is against the probability of any considerable under-estimate of its population.

CIRCULAR CAUTERISATION IN OPACITY OF THE CORNEA.

M. LOUIS VACHER of Orleans finds that in cases of corneal sclerosis or epi-scleritis better results can be obtained by circular cauterisation lightly performed with a loop of wire heated by the galvanic current than by the more usual method of passing a knife round the edge of the cornea. In one case, after eighteen months of this treatment, a patient, who had been unable to see from corneal opacity for fourteen years, recovered the power of vision. In another, a cornea which had been absolutely covered with leucoma for ten years, had in two years become sufficiently transparent for the performance of iridectomy. M. Prouff confirmed M. Vacher's statement, stating that he himself had three times operated in this manner with the most complete success.

RE-ELECTION OF MEDICAL OFFICERS OF HEALTH.

WE regret to learn that the Chesterfield rural sanitary authority have refused to receive a report from their medical officer of health under circumstances which occur more frequently than they ought to do. The question of the reappointment of Dr. Angus Mackintosh has more than once arisen, and the Local Government Board have never disguised their feeling that he is an able officer, and as such they have strongly objected to his being replaced by another officer. About a fortnight ago Dr. Mackintosh presented his authority with a report, but they refused to read it, and this because his appointment had not yet been confirmed by the Local Government Board. If they received it they held that they would thereby acknowledge him as their officer, and hence be liable to pay for his services. But in the absence of the needed confirmation of the reappointment, the auditor would have surcharged them, as he did once before. With whom the responsibility for the delay rests in this instance we cannot say; on a former occasion it rested with the local authorities concerned. But such delays are by no means unfrequent, and when surcharges are made they are almost invariably cancelled by the Local Government Board. So long as this somewhat roundabout method is adopted no wrong to any individual is done, but there is no power to make an authority pay for services rendered during the interval between the period for which

services were originally sanctioned and the reappointment the sanction for the reappointment. At the date of her letter to Dr. Mackintosh had for two weeks performed all the duties attaching to his office, and for this he will apparently receive no remuneration. In future cases it should be a rule that the arrangements for re-election should be so timed that, allowance being made for such contingencies as cause delays, all the formalities can be completed before the expiration of the current term of office.

THE DANGER OF SYNCOPE IN HOT BATHS.

IT is surprising that deaths by syncope during the use of hot baths are not more common than the coroner's court returns would show them to be. The peril of faintness by the more determination of blood to the surface of the body, thus quickly depriving the heart of its usual normal support and stimulus, is very great. In cases of muscular weakness of the heart this danger must be imminent whenever the "hot" or even the "warm" bath is used. Apart from this obvious risk, however, there is always the possibility that in weakly or too impressionable states of the nervous system the peripheral stimulation produced by the application of heat to the whole of the cutaneous extremities of the afferent nerves may so act on the centres as to arrest the evolution of energy by an inhibitory influence. It is doubtful whether we lay enough stress on this consideration when prescribing the use of such external agents as act on large areas of surface and strongly impress the nerves there commencing. We know how burns of even moderate severity may kill by the impression they produce on the centres of vitality from the periphery. There is much to learn in regard to the nature and extent of the central effects which may be thus caused. Whether for good or evil, the application of heat or cold to the whole surface is a potent measure, and one that ought not to be recklessly resorted to, more especially in cases of great susceptibility, involving such excitability of the nervous centres as often coexists with fairly good health in a weakly body.

FAMILY LIKENESS.

ANY individual may be regarded as a very complex mingling of widely different bloods. To go no further back than the grandparents, he must be composed of at least sixteen different natures. It is not to be wondered at that such remarkable combinations should lead to great variations. The wonder seems rather to be that members of a family should resemble one another as much as they undoubtedly do. Sometimes in face, sometimes in form, frequently in the gait, gesture, and tone of voice, family peculiarities make themselves apparent. To many of these traits Mr. Francis Galton has devoted his attention. His latest interest has been shown in the colour of the eye. The tints of the eye for the purposes of inquiry were divided into "light," "hazel and dark-grey," and "dark." "The heritage of peculiarity" in relation to eye-colour for any child was found to amount to one-fourth from each parent and one-sixteenth from each grandparent.

CHILDREN'S HELP FOR CHILDREN'S HOSPITALS.

As a development of the Hospital Sunday and Saturday collections, a movement has been organised amongst the Sunday-school children in Birmingham, from which the Children's Hospital in that town receives very substantial support. To Councillor Wallis belongs the credit of having suggested the idea in 1880, but its success would have been very questionable if it had not received the warmest encouragement of the Hospital Sunday Committee and the most generous and steady co-operation from its honorary secretary, Mr. W. N. Fisher. The collection was made last Sunday, and for the future it is proposed to set apart for this special object the last Sunday in June. A few weeks must elapse before all the schools pay in and the total can be cast, but already facts warrant the hope that this year's proceeds may exceed those of previous years, which were as follows:—1880, £343 11*s.* 6*d.*; 1881, £231 16*s.* 5*d.*; 1882, £266 2*s.* 4*d.*; 1883, £234 3*s.* 1*d.*; 1884, £271 5*s.* 1*d.*; 1885, £327 17*s.* 6*d.* Ministers of all religious denominations and Sunday-school superintendents have worked the scheme with unsectarian and truly benevolent zeal, and it is most satisfactory to note that advertising and printing are the only items of expense. In the future very material support may be anticipated from the Board schools, as many of their teachers have signified willingness to co-operate, and the Chairman of the Birmingham School Board has sanctioned their doing so.

EFFECTS OF DRUGS ON THE SWEATS OF PHTHISIS.

DR. ABLETSOFF, who has made a number of accurate observations on the effects of various drugs upon the sweats of phthisical patients, finds that hydrochlorate of pilocarpine, given in doses of a twentieth of a grain, produces no limitation of the sweats in a very large proportion of cases; but its use frequently causes or increases gastro-intestinal irritation and sleeplessness, and, in fact, makes the general condition of the patient worse. With doses of from one-eighth to one-sixth of a grain the diurnal and nocturnal loss of weight almost always increases, and with doses of from one-twentieth to one-tenth of a grain the loss is augmented in the majority of cases. The reasons why this drug has been recommended for phthisical patients are probably to be sought in its expectorant action; but though as a matter of fact the amount of sputum daily expectorated is increased by the drug, it has no advantages whatever over other remedies whose effects in other directions are not so deleterious. Homatropine, picrotoxin, and duboisin distinctly decrease the cutaneous perspiration in healthy subjects, the latter drug having the greatest effect. For phthisical patients, however, who are weakened by exhausting sweats, more suitable drugs will be found in agaricin and homatropine, as duboisin and picrotoxin frequently produce other and undesirable effects.

NORTH-EASTERN WATERING-PLACES.

THE new line of railway between Scarborough and Whitby will prove a great boon to the visitors of both places, as opening up some of the wildest and most romantic coast scenery in the kingdom. Robin Hood's Bay and The Peak will prove, no doubt, the favourite excursions. The former we prophesy, will ere long rise from its position of a mere fishing village to that of a well-frequented seaside resort, for, in addition to its wild coast and its beautiful inland scenery, it offers excellent sites for building, and natural advantages for dealing with the great problem of all watering-places—viz., drainage. Among the north-eastern watering-places, Saltburn has within the last few years progressed most rapidly in relation to its size, and care has also been taken with its growth to maintain the sanitary requirements of the town, and one of our Commissioners, who recently visited it together with Scarborough and Whitby, reports himself much pleased with all he saw. Saltburn is naturally much quieter than its larger neighbours, and more suited for those who require rest and quiet rather than change and amusement. The wooded glens with their picturesque streamlets, are admirably adapted for invalids who are unable to take long walks. At all the watering-places along the coast that our Commissioner had

an opportunity of visiting he was much struck by the attention now paid to sanitary details, in marked contrast to the state of affairs some ten or twelve years since—not only with respect to drainage and water-supply, but in such matters as scavenging and cleansing. At Scarborough, for instance, during Whitsun week, although the town was daily thronged with excursionists, the streets each morning were thoroughly swept and watered, and everything sweet and clean.

PERIPHERAL NEURITIS AND CHRONIC RHEUMATISM.

THE evidence in support of the theory that rheumatism—or perhaps one ought rather to say rheumatoid arthritis—is dependent on nerve lesions has hitherto been for the most part clinical, and therefore more or less hypothetical. A communication made to the Société de Biologie on the 12th ult. by MM. Pitres and Vaillard may possibly advance the question a step further. They related the results (*Progrès Méd.*, No. 25) of the examination of two subjects who during life had presented the most typical signs of arthritis deformans, with considerable osseous lesions and trophic changes of the skin and nails. The nerves of the affected limbs were found to be in a most extreme degree atrophied, exhibiting the characters of parenchymatous neuritis. It was asked whether such changes are constant in chronic rheumatism, or are they due to some accidental localisation of the rheumatism, or are they partly the cause of the osseous, muscular, and cutaneous lesions? These questions were not discussed by MM. Pitres and Vaillard, and therein they showed a wise caution, for there is no proof at all why in such advanced cases any nerve changes that are met with may not be secondary to the chronic disablement of the motor apparatus.

FOREIGN MEDICAL APPOINTMENTS.

DR. E. KRAPELIN, chief physician for mental diseases in the Dresden Hospital, formerly a pupil of Dr. von Gudden, whose recent sad death in the faithful discharge of his duty is so well known, has been appointed Professor of Psychiatry and Director of the Clinic for Mental Diseases in Dorpat, succeeding Dr. Emminghaus. Dr. Rabb has been appointed Professor of Anatomy in the German Faculty of Prague. Dr. G. Runge, who was recently "called" from Dorpat to Basle, has just been appointed Professor of Medical Chemistry in Kieff. Dr. Morosoff of Kharkoff has been nominated Professor of Operative Surgery in Kieff.

HYDROPHOBIA.

IT will be necessary for M. Pasteur to give an account of all his cases, so that every criticism may be fully answered. Another death is reported of one of the patients on whom his preventive treatment had been fully carried through. The case was that of a girl named Lagut, aged eleven, who was bitten by a dog on April 27th. After some days illness she expired on June 17th. Report says that death was due to hydrophobia, but this would require investigation. Meanwhile M. Pasteur's system is being tested in New York by Dr. Mott and Dr. Sternberg, and a Pasteur Institute is about to be founded in Milan under the direction of Dr. Barattieri. The death of a labourer is reported from Plymouth as resulting from hydrophobia. A wound was inflicted on his thumb by a small terrier four weeks before the development of the fatal symptoms. The poor fellow's case is worth special mention, because of the profuse bleeding which accompanied the infliction of the wound. It is often asserted that free hæmorrhage prevents the absorption of the virus of rabies. Although a flowing away of fluid from the wounded part does [illegible] that diminish the chances of absorption, still it must [illegible]membered that opening of bloodvessels likewise increa[illegible] the chances of infection. Moreover, under such circumstances a more rapid development of the symptoms may be accounted for.

THE MAYO NATIVE HOSPITAL.

THE report of the transactions of the Mayo Native Hospital at Calcutta and its dependent dispensaries, for the year 1885 has just been published. This hospital, intended, as its name implies, for the treatment of the native poor, was founded in 1792, and receives a monthly donation from the Government of 1000 rupees, the only condition attaching to this gift being that the nomination of the members of the Committee of the hospital be subject to the approbation of the Governor-General in Council. The foundation-stone of the building occupied at the present time was laid by Lord Northbrook in 1873, and has been open for the treatment of patients since 1874. During 1885 the aggregate number of patients treated was 2564 in-door and 179,208 out-door. In 1884 these numbers were 2451 and 181,274 respectively. The total income, including a balance of 5760 rupees from the previous year, was 64,197 rupees, and the expenditure amounted to 58,900. The generous support which the Mayo Hospital has met with from the native population of Calcutta is an eloquent testimony of the appreciation in which it is held by those for whose benefit it was founded.

COCAINE AS A DIURETIC.

DRS. DA COSTA and PENROSE of Philadelphia have been investigating the diuretic action of cocaine, and they have obtained some striking results. In all the cases but one in which observations on the urine were made a notable increase in this secretion was observed. In one case the hypodermic injection of half a grain of cocaine once a day increased the amount of urine from 24 oz. to 48 oz., and in another case a grain given by mouth thrice daily increased the urine at once from 40 oz. to 96 oz. The specific gravity of the secretion was but slightly altered; thus in one case, in which the daily amount of urine was raised from 14 oz. to 88 oz. and 72 oz., the specific gravity varied from 1020 to 1023. Abundant deposits of urates were observed, but no special estimation of the solids of the urine was made. The diuretic action was found to persist for some short time after the discontinuance of the cocaine. The authors of this paper recommend the employment of cocaine in cases of weak heart with dropsy, and in uræmia with scanty secretion of urine.

ESERINE AND PILOCARPINE IN GLAUCOMA.

M. PANAS reports to the Paris Academy of Medicine that in certain classes of glaucoma which are not benefited by operation he has had considerable success by instilling eserine or pilocarpine, and he suggests that in all cases where operative procedures fail in arresting the increase of ocular tension these agents should be tried.

WHO IS RESPONSIBLE?

IT is now some years since THE LANCET undertook an inquiry into the case of the sick in metropolitan workhouses, and the circumstances which were by this means brought to light led to important alterations and improvements. A report from Dr. Bridges, the inspector of the Local Government Board, which was read last week at a meeting of the Strand Board of Guardians, criticising and condemning the arrangements at the Edmonton Workhouse, shows that perfection is not yet attained. The chief complaint made relates to the dispensing of medicines in the workhouse, which

appears to have been very largely in the hands of the nurses. A letter published in the *Standard* subsequently from a member of the Strand Board, places the responsibility for much of the present condition of affairs upon the Local Government Board, who, he states, have neglected during six months to give their sanction to the appointment of a dispenser. That one or the other board is to blame is evident, but which?

TOXICITY OF URINE IN BRIGHT'S DISEASE.

WE have already informed our readers of M. Bouchard's researches on the toxicity of the normal urine, which promise to be of considerable value in practical medicine. M. Dieulafoy has determined that the toxicity of the urine in Bright's disease is less than in health. There are two modes in which the toxicity of the urine may be reduced. It has been clearly shown that increased oxidation possesses this power. Deficient elimination is another method, though it acts in an altogether opposite manner. In Bright's disease the poisonousness of the blood rises whilst that of the urine correspondingly diminishes. It has been suggested that in cases of Bright's disease without albuminuria this diminished toxicity of the urine might prove of service in diagnosing certain cases of unconsciousness due to uræmia. The coefficient of toxicity is reckoned as that quantity of urinary poison required to kill a rabbit of definite weight. Thus it would be possible to make mathematical calculations.

POISON FOR A PENNY.

A FEW days ago Dr. Danford Thomas held an inquest on the body of a man, aged nineteen, who died from the effects of taking rat-poison. From the evidence it appeared that he had been out of work, and had led a homeless, wandering life for more than six months. A police-constable deposed that he came to the King's-cross Police Station and stated that he had taken a pennyworth of phosphorus paste. He was seen by the police divisional surgeon, who ordered his removal to the Royal Free Hospital, where he died after several days of intense suffering from syncope, the result of fatty degeneration of the heart and other organs. The resident medical officer stated that there was no difficulty in procuring phosphorus paste, and that *a fatal dose could be procured from any oilman for a penny*. Comment on this would be superfluous. The jury returned a verdict of "Suicide while of unsound mind," without appending any rider.

THE HOSPITAL SUNDAY FUND.

THE totals of the first four days' receipts up to Thursday evening amounted to £18,000, as compared with £14,000 at a similar period last year. Some large collections are paid this year for the first time since the establishment of the Fund.

THE QUEEN has been pleased to approve of the appointment to the Order of the Indian Empire of Mr. G. Watt, M.B., C.M. Glas., and J. W. Tyler, M.D., F.R.C.S. Ed., for services in connexion with the Colonial and Indian Exhibition.

DR. WENDELL HOLMES, in company with the Right Hon. John Bright and others, received the honorary degree of D.C.L. at the Sheldonian Theatre, Oxford, on Wednesday, in the presence of the Prince and Princess Christian.

SIR JAMES PAGET, Bart. was yesterday, by 57 votes out of 64, elected a Foreign Associate of the French Academy of Medicine. Dr. Charles West of London, and M. van Beneden, of Brussels, were the other candidates.

THE PRESENT ASPECT OF THE CHOLERA QUESTION.[1]

BY PROF. DR. MAX VON PETTENKOFER,
OF MUNICH.
Abstract supplied, by special permission of the Author, by
HENRY KOPLIK,
OF NEW YORK.

DR. VON PETTENKOFER, in the above work, discusses the transactions in the scientific world on the subject of cholera since the year 1883. He elaborates his views more from an epidemiological standpoint, as combined with the teachings of the vast advances in the subject of bacteriology at the present day. The work thus embraces a discussion of the two conferences in Berlin, the conference in London in 1885, the Sanitary Congress in Rome, June, 1885, and the Transactions of the Academy of Medicine, Paris, 1883-85. The author has divided his work according to the following schema:—I. The Autochthonists. II. Contagionists: (1) The infection of physicians and nurses through the sick; (2) Excrement of the sick as a seat of infectious matter; (3) House epidemics in hospitals and barracks; (4) Linen of cholera patients; (5) Cholera on ships; (6) Spread of cholera through intercourse on land; (7) Spread through drinking water. III. The Cholera Theories from a Bacteriological standpoint. IV. The Localists: (*a*) The influence of local disposition; (*b*) Influence of time. V. The Prophylactic Measures.

There are two main views at the present day concerning the nature of cholera. One that the disease, originally endemic in India, has been introduced into the different countries of Europe through the agency of a specific micro-organism transported thence through human intercourse (cholera Asiatica) Another view, that of the Autochthonists, is that cholera may be caused in other lands, as in India, by telluric and atmospheric conditions and special circumstances; appearing in isolated cases as cholera nostras, and at times becoming epidemic. The author proposes for the first the term of "Ephodist" (ἔφοδος—intercourse), and rejects as misleading the term "Contagionist."

The *Ephodists* hold that the specific micro-organism, the cause of cholera, is endemic in lower Bengal, where its history dates either since or previous to 1817. From here the germ is carried through human intercourse into different localities. It does not thrive outside its endemic locality, and the micro-organism must be introduced anew each time in order to cause an epidemic. The Ephodists are further divided into two schools: the Contagionists, who attribute to cholera patients the power of generating a specific infectious matter; and the Localists, who hold that cholera patients and their excretions are not infectious, but that only the local conditions existing at the time are capable of generating an epidemic by favouring the growth of the imported infectious matter.

The *Autochthonists*, as opposed to the Ephodist view, that cholera is spread through the agency of human intercourse and traffic, are headed by James Cunningham working in Calcutta, and Jules Guérin in Paris. Though both of these men stand almost alone in their theories at the present day, yet the facts collected by them remain as firm as ever. Cunningham especially, with his long and vast experience, commands attention. Working on the site of the disease, he has, by the introduction of practical prophylactic measures, been able to diminish the frequency of the disease in the barracks and prisons of India. These measures presuppose that the cholera patients produce nothing capable of making the healthy ill, nor do they recognise in any way the fundamental teachings of the Contagionists. Cunningham shows by large statistics that the frequency of cholera in India is less dependent on cases of cholera, which are always to be found in India, than upon the particular *locality* and *time*. The latter are much more diverse and changeable than the human economy, which for the Contagionists is at the same time the centre of manifestation and origin of the disease. Moreover he has shown that the

[1] Résumé from the German work (in the press). "Zum Gegenwärtigen Stand der Cholerafrage," by Prof. Dr. Max von Pettenkofer, of Munich.

spread of cholera outside its endemic localities does not present the picture of a gradual extension of disease from a central point, but rather that of isolated outbursts in a comparatively small number of inhabited cities and villages.

If in India the cholera spreads in an epidemic manner outside its endemic locality, it does so, not in the direction of intercourse and travel, but rather in a contrary direction. The system of drainage in the upper provinces, carrying the refuse of cholera patients, runs in a direction contrary to that of the spread of the epidemic. Railroads in recent times have also not influenced the direction taken by the disease, nor the rapidity of its extension or the frequency of the epidemic, as may be seen by comparing the statistics of to-day with those obtained before the construction of railroads. The same may be argued in the case of ships. If, against these facts of Cunningham, Koch argues that the frequency of cholera epidemics is greater in such districts as Peneschab since the opening of railroad lines, we must conclude that in this particular instance the frequency is more apparent than real, inasmuch as, perhaps, the statistics are more accurate to-day than in former times. The author is thus disposed to fully agree with Cunningham in the above particulars. Jules Guérin, in maintaining that the influence of human intercourse is a factor of no moment in cholera epidemics, cites the fact that in Paris during the Exhibition of 1867 there were no cases of cholera, though the city was filled with thousands of strangers, some coming from the localities where the cholera was at the time in progress, and though the disease existed in many of the neighbouring countries. Netten Radcliffe showed that at this time the cholera existed in Tunis, with which France was in close relationship, and in the neighbouring Italian cities where it was at its height. In Paris there was no quarantine. Cholera existed also north of Paris, in Zurich, Dusseldorf, and the Rhinelands. The argument of Fauvel, the opponent of Guérin, that the inhabitants of Paris had acquired a certain immunity from the disease on account of a previous epidemic in 1865, can scarcely be considered tenable; many thousands of people lived in Paris in 1867 who were not subjected to the influences of the epidemic of 1865.

An important point brought forward by the Autochthonists is the wide separation of the first cases in the outbreaks of local epidemics. The cases are scattered without the slightest connexion with one another. In the cholera epidemics in Toulon and Marseilles in 1884, the author maintains that evidence points to the existence of cholera in Marseilles before the arrival of the student, to whom the spread of the disease in the latter place was attributed. Rather is it more plausible that the student from Toulon contracted his cholera through local conditions existing in Marseilles. The disease manifested itself, in his case, three days after his arrival there. [Besnier, in discussing the spread of cholera epidemic since 1832, denies that such spread was commensurate with the amount of intercourse with infected localities.]

The author at this stage of the work enters into the definition of infectious diseases. Under infectious disease are included those diseases caused by the entrance of a specific infectious matter into the body. Such specific infectious matter is found by the light of recent research to be micro-organisms, or products of the same. In England we have a classification of diseases into contagious (scarlet fever, measles) and infectious, the latter being subdivided into transmissible and non-transmissible. An infectious disease being here understood as a disease caused by infectious matter from the soil, water, or air, these diseases may be "transmissible" from place to place (cholera); others are "non-transmissible" (malaria, pure miasmatic.) In Germany we have the division into contagious, miasmatic, and contagious-miasmatic. These terms, contagious, miasmatic, and infectious are, on the whole, very misleading in the light of recent bacteriological research and from an epidemiological standpoint. The author would propose that under the specific term "Infectious matter" (*Infectionstoffe*) we include in the future the words "contagium" and "miasm." This infectious matter may be distinguished as entogen or ektogen, according to whether the infectious matter passes directly from the sick to the healthy, or the bacterium capable of infection, or its products, develops in the surroundings of the infected person before passing into the economy (ektogen). Inasmuch as some organisms can develop after both fashions, Stricker has proposed a third term—amphigen—to supplement the above. Returning to the [illegible] asserted by Autochthonists (Guérin), that at the begin[illegible] of epidemics we have to deal with isolated cases which [illegible] no connexion with each other, the author has found [illegible]t in the case of the three epidemics in Munich in 1836-37, 1854, and 1873, the exact mode of introduction of the germ could not be established. In these three epidemics, however, the cases were found always in particular streets of the city—speaking more for the Autochthonists than for the Contagionists. Moreover, the railroads of the city lay in an opposite direction to the localities where the epidemics began. The author, however, does not at all accept the Autochthonist doctrines, for the following reasons:—

The Autochthonists (Cunningham, Guérin) do not recognise that modern bacteriology has proven that all infectious diseases are caused by a specific micro-organism (tuberculosis, milzbrand, &c.) We must accept the view that the cholera bacterium is an "ens sui generis" which now exists in the world and can be spread from place to place. It may have originally developed under favourable conditions from a non-pathogenic micro-organism in a way similar to what we find to be the case in the history of the plant world. While Macpherson thinks that cholera has been endemic in India from the earliest times, Koch and Semmelink think that cholera first appeared in India in 1817. At whatever time it originated, at least from 1817, the germ could be conveyed from its place of origin and by human intercourse spread over Europe. The questions, however, arise—(*a*) Does it thrive in the new localities to which it is brought, and if so how long? (*b*) Does the germ, as in India, become perennial in its new home, or does it after a time die out, and must it be brought in anew? The Autochthonists can eliminate the question of human intercourse by supposing that the cholera germ can develop in other places as in India (autochthon), but being subject to other conditions it causes epidemics with less regularity and with longer intervals. Besnier, in the case of Paris, has supposed a certain space of latency to exist during which the germ develops. The periods between the outbursts of cholera can be of different duration, and a fresh introduction of the germ from without is not necessary. The author thinks that from his own studies of the epidemics in such places as Malta and Gozo islands the cholera germ does not in its new home become perennial, but dies out, and must be brought by human intercourse anew into the locality in order to develop and cause an epidemic. The Ephodists, both localists and contagionists, admit the influence of human intercourse in spreading cholera. It can never be proven that a locality recently attacked with cholera has had no communication with a place where cholera is existing; and, moreover, where cholera patients have come to large cities and died, there have always been a number of pendant cases to those original ones where the subsequent investigation showed the case succeeding the first to have been in personal close relation with the sick. These facts must lead to a complete rejection of the autochthon theory. It must be admitted that there is something adhering to persons coming from localities where cholera exists which is capable of spreading the disease in a new spot.

(To be continued.)

Pharmacology and Therapeutics.

LANOLINE.

WE have received two specimens of lanoline—one which contains 20 per cent. of water, and one quite free from water. The profession is indebted to Dr. Oscar Liebreich for this new basis for ointments. Although vaseline has met with great favour, two objections have been urged against it. On the one hand, it is said to be an irritant to some skins; and it is further alleged that it has but slight power of penetration, so that active ingredients of vaseline ointments are not readily absorbed. From the experiments of Dr. Liebreich, it appears that lanoline possesses great powers of penetration, and that when employed as the vehicle of active drugs they are absorbed from the skin with great readiness; and it promises, therefore, to be extremely useful in all cases where alkaloids are used in the form of ointments. Lanoline is a cholesterine fat—the natural fat of

the skin; it is neutral in reaction, and decomposes with great difficulty. It is improved by the addition of from 5 to 10 per cent. of fat or glycerine.

HYDRASTIS CANADENSIS.

The current number of the *Therapeutic Gazette* contains an able article on the Physiological Action and Therapeutic Uses of Hydrastis Canadensis. To Schatz is due the credit of having first introduced it into gynæcological practice, whilst Fellner was the first to subject it to a thorough physiological examination. From experiments recently published it would appear that its action varies according to the mode of administration. Fellner finds that large doses administered to dogs under the influence of curare induce lowering of the blood-pressure and slowing of the pulse, followed by rise of pressure and quickening of the pulse with irregularity of the heart's action. Medium doses produce similar phenomena, but the blood-pressure rises more in the first stage and falls less at the end of the second. Small doses increase the general blood-pressure, whilst subcutaneous injections and enemata, even in large doses, act similarly to small doses injected into the veins. It is probable that hydrastis exerts its effects chiefly on the vaso-motor nerve centres, but it is also a direct heart poison. Practically, it is found to be useful in many catarrhal conditions and in certain forms of gastric and uterine disturbance.

SALOL.

This new compound, introduced by Nencky, is a derivative of salicylic acid, one atom of hydrogen of which has been replaced by the phenol group (*Pharmaceutical Journal*). Possessing antipyretic and antiseptic properties, it is hoped that it may prove of service in cases in which the salicylate of soda is badly borne. Its physical characters are those of a white powder of faintly aromatic odour, almost insoluble in water, and perfectly tasteless. In the organism the compound becomes split up into the salicyl and phenol elements; both may be detected in the urine, which becomes very dark, as happens after the ingestion of carbolic acid, of which salol contains 38 per cent. The spliting of the compound is believed to take place in the duodenum, under the influence of the pancreatic digestion. It is remarkable that no toxic symptoms appear to have resulted from the employment of salol.

CONDURANGO IN GASTRIC DISEASES.

Dr. Enrique Suñer writes to *El Genio Medico* that, having recently employed Condurango bark in the treatment of several cases of gastric carcinoma and catarrh, he has found it very beneficial. He gives a tablespoonful of the infusion every two hours, and in all cases the pain was decidedly mitigated and the appetite and digestion improved. In most cases of mere gastric catarrh the painful nausea and vomiting ceased, and subsequently the patients recovered from the mental depression which was due to the acute gastric disturbance. In the malignant cases, of course, nothing could be hoped for but alleviation of pain, and some improvement in the ability to take and retain nourishment.

PHOSPHORUS IN INTERMITTENT FEVER.

A Russian provincial practitioner, Dr. Sochinski, states that during a rural practice of five years he has found phosphorus a valuable remedy in intermittent fever. He prescribes the oleum phosphoratum in the form of emulsion, a drachm in six ounces, of which a tablespoonful is given three times a day. This, he says, never produces unpleasant effects, and is in his experience superior to tincture of iodine, tincture of eucalyptus, and even to arsenic, cinchonine, and resorcine, though scarcely equal to quinine or carbolic acid and corrosive sublimate. It is, however, a simple and a very convenient remedy for out-patients in dispensary or parochial practice.

ETHOXYCAFFEINE.

This body is caffeine in which one atom of hydrogen is replaced by the group C_2H_5O. Alkalies precipitate its salts from their solutions. Hypodermic injections in rabbits gave indications of a narcotic action. M. Dujardin-Beaumetz has administered this agent in cases of severe headache, and with beneficial results. Its insolubility is an objection, as is also its tendency, with other allied bodies, to cause gastric symptoms. Most of these difficulties are overcome by dissolving the drug in salicylate of soda and adding some carminatives. The largest dose given was twenty-five centigrammes. Guarana and Paullinia owe their value in megrim to their containing caffeine.

SALICYLATE OF BISMUTH.

Bismuth in the form of carbonate or trisnitrate is one of the few valuable remedies we possess. Dr. Solger now claims for the basic salicylate of this metal a special value in cases of diarrhœa and chronic intestinal catarrh. He administers about twenty grains every eight hours, and attributes its beneficial action mainly to its disinfectant properties. In some invalids, malaise, furred tongue, and abdominal pains are said to be caused by the drug, though a small dose of castor oil readily removes the toxic effects without requiring its discontinuance.

URETHAN.

M. Coze has investigated the physiological action of urethan on frogs, guinea-pigs, rabbits, and dogs. He finds that it is antagonistic in its action to strychnia. It causes muscular relaxation and induces sleep; slows the pulse and the respiration, whilst lowering the temperature. As it has no irritant local action, it can be conveniently used for hypodermic injection; it does not disturb the secretions or the nutrition; its use in convulsions and in tetanus is recommended.

IODOFORM IN ERYSIPELAS.

Dr. A. J. Solitski mentions in a Russian military medical journal the satisfactory results he has obtained by treating erysipelas, whether idiopathic or traumatic, by means of an iodoform ointment of the strength of from 1 to 8 or 1 to 10. The effect of this application was seen in the reduction of the swelling, the relief of the pain, the diminution of the intensity of the erythema, and the reduction of the high temperature.

PARTHENINE.

According to M. Guyet, parthenine is not a simple substance, but of complex nature, like scillitine and the amorphous digitalines. It does not appear to have any antipyretic action, but seems to be useful in some cases of neuralgia.

PILIGANINE.

M. Adrian has discovered a new alkaloid in Lycopodium Saussures. It has an alkaline reaction, and emits white vapours, like ammonia, in the presence of hydrochloric acid. It causes powerful emesis and catharsis.

UNIVERSITY OF LONDON.

A MEETING of Convocation of the University of London was held on June 29th, Dr. F. J. Wood, Chairman of Convocation, presiding.

The nomination of a list of three graduates, "to be submitted to Her Majesty for the selection therefrom of a Fellow of the University" was proceeded with, the scrutineers eventually reporting that Dr. Wilks had received 428 votes, Mr. Magnus 379, and Professor Thistleton Dyer 187; whilst 114 voting papers were cancelled for non-compliance with the regulations.

A motion respecting the celebration of the jubilee of the University, standing in the name of Mr. Whitehead, was withdrawn; and in its place a resolution proposed by Mr. Howse was carried, referring the question to the Annual Committee, with power to confer with the Senate upon it.

Mr. Newson's Special Committee of seven members to consider the regulations for the Law Examinations was approved, the members nominated being James Anstie, B.A., Q.C.; J. B. Benson, LL.D., B.A.; E. H. Busk, M.A., LL.B.; B. Kisch, M.A., B. Sc.; T. L. Mears, LL.D., M.A.; T. B. Napier, LL.D.; F. A. Philbrick, B.A., Q.C.

A motion by Mr. MAGNUS to pass to the business of the extraordinary meeting—namely, the resumption of the adjourned debate upon the scheme on the constitution of the University, was resisted by Mr. Tyler, whose resolutions upon the same subject stood next upon the agenda. On a division, there voted for the motion 44, against 16.

Mr. MAGNUS therefore moved, and Mr. ANSTIE seconded the following resolution, recommended on page 6 of the Report of the Special Committee:—(C.) "That Convocation approves of the proposals for the constitution of the Senate of the University contained in Section 2 of the subjoined scheme." This section runs as follows:—The Senate to consist of—(*a*) Chancellor, to be appointed by the Crown.

(*b*) Vice-Chancellor, to be elected by the Senate annually from amongst its members. (*c*) The following members *ex-officio*: Chairman of Convocation, Chairman of Council of Education, Chairman of each of the four Boards of Studies. (*d*) Ordinary members, to be appointed as follows: Six by the Crown, eight by Convocation, four by the Council of Education, and one by each of the seven following institutions: University College, King's College, Royal Society, Royal College of Physicians of London, Royal College of Surgeons of England, Council of Legal Education and Council of Incorporated Law Society. The ordinary members to hold office for a period of four years, and to be re-eligible. The Senators elected by Convocation to be elected by members of Convocation voting in their respective Faculties. Two members to be elected by the members of each of the four Faculties. The Senate to have the control and management of the University.

Mr. ROUND contended that this scheme would give a preponderating influence to teachers, and would alter the character of the University. He moved the omission of University College, King's College, and the two Legal Councils; and also to provide that only two out of the eight representatives of Convocation should be teachers.

Mr. LYNN seconded the amendment, and characterised the scheme as a proposal to tear the University up by the roots, and as infallibly tending to lower the value of the degrees. The University might develop in many directions, such as founding laboratories, observatories, &c., without constituting itself another teaching body, but remaining the highest possible examining board.

Dr. SEGRELL, LL.D., pointed out that the representation of Convocation on the Senate was not sufficient, and he did not see the need for inviting other bodies to share privileges at present restricted to the Crown and Convocation.

Mr. TYLER said the scheme would create a new university which would be swamped by teachers. He did not see that the Colleges of Physicians and Surgeons had any claim to be represented on the Senate, and contended that University College was already well represented, whilst King's College sends so few graduates as not to constitute a claim. He also objected to the Royal Society and other bodies sending senators, and believed the best plan would be to maintain the existing Senate with greater proportionate members elected by Convocation.

Mr. MACDOWALL defended the scheme, and pointed out that neither the Royal Society nor the Colleges of Physicians and Surgeons would be likely to send men engaged in teaching to the Senate.

Mr. NESBITT thought that power would be given into the hands of teachers, and the University would lapse into the state of the Scotch universities. He denounced the proposals as revolutionary and opposed to the traditions of the University, whilst they would certainly entail a lowering of degrees. He objected to the four years' tenure of office, and advocated life tenure, as at present; and he also objected to the representatives of Convocation being elected by each faculty, and not by the whole body.

Dr. T. B. NAPIER, LL.D., said there was no direct representative of the teaching bodies except in the case of the two colleges. The Council of Education consisted largely of the examiners of the University, and but one-third of it would be teachers. Altogether, he did not think the Senate would have more than five of its members directly representing the teaching element.

Mr. NEWSON opposed the scheme on the ground that Convocation had so small a representation, and he totally objected to the paragraph giving all the control and management of the University to the Senate.

Mr. ANSTIE, Q.C., defended the scheme. Convocation would be largely represented on the Council of Education, both directly and through the examiners, most of whom are members of the University. It was needful for the University to be fully informed of the views of teachers, and care could be taken that the interests of teachers did not get the better of their judgment. He ridiculed the notion that the inclusion of representatives from the Royal Society and the two great London colleges would tend to lower the value of degrees, and trusted that Convocation would not be actuated by such small motives and jealousies as had been expressed. He pointed out that the constituent colleges would comprise many institutions, and that the scheme would remove the complaints that provincial colleges were disregarded. The section was vital to the scheme, and the introduction of these bodies on the Senate was of the highest consequence to the University.

Mr. HINTON thought provision should be made for replacing any of these bodies, if necessary, by others, and Mr. COTTON opposed the scheme.

On a show of hands, a large majority voted against the amendment; but a division being called for, there voted for the amendment 1, against 42.

On the original resolution being put, Mr. NEWSON moved the omission of the words, "The Senate to have the control and management of the University." This was seconded by Mr. UPJOHN, supported by Mr. TYLER, but rejected by a large majority.

Mr. HINTON moved the omission of the clause providing for election by the Faculties, but this was not seconded; and a similar motion by Mr. NESBITT was lost.

The original resolution was then put and carried by a large majority.

Mr. MAGNUS then moved the adoption of the following resolution, recommended on page 8 of the Report of the Special Committee (D) "That Convocation approves of the proposals contained in Section 6 of the subjoined scheme for enabling the University to assist in the promotion of higher university education." He said that the University should now undertake other functions than mere examining, and do something to encourage learning for its own sake. He had no doubt that it would obtain funds, for it was absolutely necessary to be freed from State control, and they had a right to ask for a permanent State endowment. With the sole exception of the Normal School of Science—which is devoted to the training of certificated Government teachers—London receives no aid from the State for teaching purposes. He believed that if the University were placed on a different basis, there would be no lack of donations and bequests, which would render the University an educational power of which the country would be proud, and one worthy of the metropolis.

Mr. ANSTIE seconded the resolution.

Mr. TYLER pointed out that the University already administered the Brown bequest. He also objected to the proposal to grant honorary degrees. Some discussion arose upon this latter point, and eventually an amendment striking out the clause referring to honorary degrees was carried.

Dr. FOSTER MORLEY thought, in fairness to the University and King's Colleges, who on the foundation of the University surrendered their powers to grant degrees, that these bodies should be consulted before the University took on teaching function. But his amendment to that effect was not seconded, and the resolution was carried.

The final resolution, (E) "That the Report and Scheme be adopted as a basis of conference with the Senate, and that the Special Committee be reappointed with power to confer with the Senate thereon," was then moved by Mr. Magnus, seconded by Mr. Anstie, and carried, Mr. Tyler protesting that the scheme would be disastrous to the University.

The House then adjourned after a sitting which had occupied three hours and a half, and Mr. Magnus received many congratulations upon the manner in which he had successfully carried the scheme of his committee, involving as it does such radical changes in the constitution and functions of the University.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the Fellows of the College was held on Tuesday last, at 5 P.M., the President, Sir William Jenner, Bart., K.C.B., in the chair. A licence was granted to Mr. John Ernest Trask. A communication was read from the Royal College of Surgeons, stating that the Council had appointed delegates to confer with those nominated by the College of Physicians in reference to the future use of the vacant plot on the Embankment after the erection of the Examination Hall.

The next business on the agenda was the further consideration of the report of the Croonian Trust Committee, which had been discussed and postponed at two previous meetings. The adoption of the report by which the increased income of the Trust would be devoted to the promotion of "anatomy, physiology, and pathology, in their bearing on therapeutic science, with a view to the more

efficient prevention, control, and cure of disease," was moved by Sir Risdon Bennett, and seconded by Dr. Balfour.

Dr. Dickinson moved, and Dr. Wilks seconded, the amendment standing in Dr. Bristowe's name—viz.: "That there be three Croonian Lectureships: one of these to be simply the continuation of the present Croonian Lectureship, to be generally held by a Fellow of some years' standing, who shall be called, as heretofore, 'The Croonian Lecturer'; the other two to be devoted specially to the promotion of original research. That one of the two Research Lectureships be devoted to the investigation and discussion of subjects connected with the anatomy and physiology of disease, and that the lecturer be styled 'The Croonian Professor of Pathology.' That the other of the two Research Lectureships be devoted to the investigation and discussion of subjects connected with clinical medicine and the treatment of disease, and that the holder be termed 'The Croonian Professor of Clinical Medicine and Therapeutics.' That each of the Research Lectureships be tenable for one, two, or three years, at the discretion of the President; and that the number of lectures to be delivered annually in each case be not less than three or more than six." This was lost on a division.

Dr. Quain then moved, and Dr. Wilson Fox seconded, another amendment: "That there shall be one or more Croonian Lecturers appointed by the College, who shall be required to deliver lectures on one or more subjects in anatomy, physiology, and pathology, with a view to the prevention, control, and cure of diseases. That the College shall devote the funds derived from the Croonian Trust (1) to the payment of such lecturer or lecturers, and (2) to the contribution of such sums as the College may think fit towards the promotion of scientific investigation on the subjects of the lectures." This was passed by a large majority.

A further amendment to change the words "with a view to the" for "with the special object of the more efficient" was lost, and the insertion of the word "chemistry" was also objected to, inasmuch as it might entail some legal difficulty in passing the scheme through the Court of Chancery.

Dr. West's proposal to alter Bye-law 69, affecting the powers of the Council, was rejected by a large majority.

The Registrar then moved: "That it be referred to the Committee of Management to consider what staff should be appointed, and under what conditions, for the efficient management and conduct of the business of the Examination Hall, and to report to the two Colleges," which was carried, and the proceedings terminated.

A BILL TO AMEND THE MEDICAL ACTS.

BE it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

I. *Short title and construction.*—This Act may be cited as the Medical Act, 1886, and shall be construed as one with the Medical Acts.

PART I.—ADMISSION TO MEDICAL PRACTICE AND CONSTITUTION OF GENERAL COUNCIL.

Qualifying Examinations.

II. *Examination before registration.*—On and after the appointed day a person shall not be registered under the Medical Acts in respect of any qualification referred to in any of those Acts, unless he has passed such qualifying examination in medicine, surgery, and midwifery, as in this Act mentioned.

III. *Qualifying examinations held by medical authorities.*—(1) A qualifying examination shall be an examination in medicine, surgery, and midwifery held, for the purpose of granting a diploma or diplomas conferring the right of registration under the Medical Acts, by any of the following bodies—that is to say:—(*a*) Any university in the United Kingdom, or any medical corporation legally qualified at the passing of this Act to grant such diploma or diplomas in respect of medicine and surgery; or (*b*) any combination of two or more medical corporations in the same part of the United Kingdom who may agree to hold a joint examination in medicine, surgery, and midwifery, and of whom one at least is capable of granting such diploma as aforesaid, in respect of medicine, and one at least is capable of granting such diploma in respect of surgery; or (*c*) any combination of any such university as aforesaid with any other such university or universities, or of any such university or universities with a medical corporation or corporations, the bodies forming such combination being in the same part of the United Kingdom.—(2) The standard of proficiency required from candidates at the said qualifying examinations shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery; and it shall be the duty of the General Council to secure the maintenance of such standard of proficiency as aforesaid; and for that purpose such number of inspectors as may be determined by the General Council shall be appointed by the General Council, and shall attend, as the General Council may direct, at all or any of the qualifying examinations held by any of the bodies aforesaid.—(3) Inspectors of examinations appointed under this section shall not interfere with the conduct of any examination, but it shall be their duty to report to the General Council their opinion as to the sufficiency or insufficiency of every examination which they attend, and any other matters in relation to such examination which the General Council may require them to report; and the General Council shall forward a copy of every such report to the body or to each of the bodies which held the examination in respect of which the said report was made, and shall also forward a copy of such report, together with any observations thereon made by the said body or bodies, to the Privy Council.—(4) An inspector of examinations appointed under this section shall receive such remuneration, to be paid as part of the expenses of the General Council, as the General Council, with the sanction of the Privy Council, may determine.

IV. *Withdrawal from medical authorities of right to hold qualifying examinations.*—(1) If at any time it appears to the General Council that the standard of proficiency in medicine, surgery, and midwifery, or in any of those subjects or any branch thereof, required from candidates at the qualifying examinations held by any of the bodies for the time being holding such examinations is insufficient, the General Council shall make a representation to that effect to the Privy Council, and the Privy Council, if they think fit, after considering such representation, and also any objections thereto made by any body or bodies to which such representation relates, may by order declare that the examinations of any such body or bodies shall not be deemed to be qualifying examinations for the purpose of registration under the Medical Acts; and Her Majesty, with the advice of her Privy Council, if upon further representation from the General Council, or from any body or bodies to which such order relates, it seems to her expedient so to do, shall have power at any time to revoke any such order.—(2) During the continuance of any such order the examinations held by the body or bodies to which it relates shall not be deemed qualifying examinations under this Act, and any diploma granted to persons on passing such examinations shall not entitle such persons to be registered under the Medical Acts, and any such body shall not choose either separately or collectively with any other body a member of the General Council; and the member (if any) for the time being representing such body in the General Council shall, unless he was chosen by such body collectively with any other body not subject to an order under this section, be suspended from taking part in the proceedings of the General Council.

V. *Qualifying examinations held by medical corporation, with assistant examiners.*—(1) If a medical corporation represents to the General Council that it is unable to enter into such combination as is in this Act mentioned for the purpose of holding qualifying examinations, and the General Council is satisfied that the said medical corporation has used its best endeavours to enter into such combination as aforesaid, and is unable to do so on reasonable terms, it shall be lawful for the General Council, from time to time, if they think fit, on the application of such corporation, to appoint any number of examiners to assist at the examinations which are held by such corporation for the purpose of granting any diploma or diplomas conferring on the holders thereof, if they have passed a qualifying examination, the right of registration under the Medical Acts.—(2) It shall be the duty of the said assistant examiners to secure at the said examinations the maintenance of such standard of proficiency in medicine, surgery, and midwifery as is required under the foregoing provisions of this Act from candidates at qualifying examinations, and for that purpose the said assistant examiners shall have such powers and perform such duties in the conduct of those examinations as the General Council may from time to time by order prescribe; and any examination held subject to the provisions of this section shall be deemed to be a qualifying examination within the meaning of this Act.—(3) Assistant examiners appointed under this section shall receive such remuneration, to be paid by the medical corporation at whose examinations they take part, as the General Council determine.—(4) A medical corporation shall have power to admit to its examinations assistant examiners appointed under this section, and to conduct its examinations in accordance with the requirements of this section and of any orders made thereunder, anything in any Act or charter relating to such corporation to the contrary notwithstanding.

Effect of Registration.

VI. *Privileges of registered persons.*—On and after the appointed day a registered medical practitioner shall, save as in this Act mentioned, be entitled to practise medicine, surgery, and midwifery in the United Kingdom, and (subject to any local law) in any other part of Her Majesty's dominions, and to recover in due course of law in respect of such practice any expenses, charges in respect of medicaments or other appliances, or any fees to which he may be entitled, unless he is a fellow of a college of physicians, the fellows of which are prohibited by bye-law from recovering at law their expenses, charges, or fees, in which case such prohibitory bye-law, so long as it is in force, may be pleaded in bar of any legal proceeding instituted by such fellow for the recovery of expenses, charges, or fees.

Constitution of General Council.

VII. *Members of General Council.*—(1) After the passing of this Act the General Council shall consist of the following members—that is to say:—Five persons nominated from time to time by Her Majesty, with the advice of her Privy Council, three of whom shall be nominated for England, one for Scotland, and one for Ireland. One person chosen from time to time by each of the following bodies:—The Royal College of Physicians of London, the Royal College of Surgeons of England, the Apothecaries Society of London, the University of Oxford, the University of Cambridge, the University of London, the University of Durham, the Victoria University, Manchester, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, the University of Edinburgh, the University of Glasgow, the University of Aberdeen, the University of St. Andrews, the King and Queen's College of Physicians in Ireland, the Royal College of Surgeons in Ireland, the Apothecaries Hall of Ireland, the University of Dublin, the Royal University of Ireland; three persons elected from time to time by the registered medical practitioners resident in England; one person elected from time to time by the registered medical practitioners resident in Scotland; one person elected from time to time by the registered medical practitioners resident

in Ireland.—(2) The provisions of this section relating to the representation of the Universities of Edinburgh and Aberdeen shall take effect on the occurrence of the first vacancy in the office of the person representing those universities at the time of the passing of this Act, and the provisions of this section relating to the representation of the Universities of Glasgow and St. Andrews shall take effect on the occurrence of the first vacancy in the office of the person representing such last-mentioned universities at the time of the passing of this Act; but nothing in this section shall affect the duration of the term of office of any person who at the time of the passing of this Act is a member of the General Council.

VIII. *Regulations as to election of representatives of the medical profession.*—(1) The members of the General Council representing the registered medical practitioners resident in the several parts of the United Kingdom (in this section referred to as "direct representatives") shall themselves be registered medical practitioners; they shall be elected to hold office for the term of five years, and shall be capable of re election, and any of them may at any time resign his office by letter addressed to the President of the General Council, and upon the death or resignation of any one of them, some other person shall be elected in his place; but the proceedings of the General Council shall not be questioned on account of a vacancy or vacancies among the direct representatives.—(2) Each direct representative shall be a member of the branch council for the part of the United Kingdom in which he is elected; he shall also be entitled to fees for attendance and travelling expenses to the same extent as other members of the General Council are entitled to the same.—(3) The President of the General Council, or any other person whom the General Council may from time to time appoint, shall be the returning officer for the purpose of elections of direct representatives, and such returning officer shall, some time not less than six weeks nor more than two months before the day on which the term of office of any such representative will expire, and as soon as conveniently may be after the occurrence of any vacancy arising from the death or resignation of any such representative, issue his precept to the branch council for that part of the United Kingdom in which such representative was elected, requiring the said branch council to cause a representative to be elected by the registered medical practitioners resident in that part of the United Kingdom within twenty-one days after the receipt of the precept of the returning officer.—(4) The election shall be conducted in such manner as may be provided by regulations to be made by the Privy Council, provided as follows: (*a*) The nomination shall be in writing, and the nomination paper of each candidate shall be signed by not fewer than twelve registered medical practitioners; and (*b*) the election shall be conducted by voting papers, and it shall be the duty of the branch council in any part of the United Kingdom in which an election is to be held to cause a voting paper to be forwarded by post to each registered medical practitioner resident in that part at his registered address, but the election shall not be rendered void by reason of the omission of the branch council to cause such voting paper to be forwarded in any particular case or cases, and any registered medical practitioner to whom a voting paper has not been sent in pursuance of this Act may on application to the registrar of the said branch council obtain one from him; and (*c*) any registered medical practitioner entitled to vote at such election may vote for as many candidates as there are representatives to be elected.—(5) Each branch council shall certify to the returning officer the person or persons elected by the registered medical practitioners resident in the part of the United Kingdom to which such branch council belongs.—(6) A direct representative elected in the place of any such representative retiring on the expiration of the period for which he was elected shall come into office at the expiration of that period, and a direct representative elected to fill a vacancy caused by the death or resignation of any such representative shall come into office on the day on which he is certified by the branch council to the returning officer to have been elected.—(7) The expenses attending the election of a direct representative shall be defrayed as part of the expenses of the branch council for that part of the United Kingdom in which such representative is elected.—(8) For the purpose of the first election of direct representatives the returning officer shall, in the course of such period of seven days (ending not later than the fifteenth day of November next succeeding the passing of this Act) as the Privy Council may appoint, issue his precept to the branch council in each part of the United Kingdom, requiring such branch council to cause the proper number of representatives to be elected in the part of the United Kingdom to which such branch council belongs, within twenty one days after the receipt of the said precept; and the said representatives shall come into office on the first day of January, one thousand eight hundred and eighty-seven.

IX. *Election of President of General Council.*—The General Council from time to time on the occurrence of a vacancy in the office of president of the General Council shall elect one of their number to be president for a term not exceeding five years, and not extending beyond the expiration of the term for which he has been made a member of the said Council, but nothing in this Act shall affect the duration of the term of office of the person who at the time of the passing of this Act is president of the General Council.

Revision of constitution of General Council.—(1) The General Council may at any time represent to the Privy Council all or any of the following matters: (*a*) That it is expedient to confer on any university or other body in the United Kingdom capable of granting a medical diploma, not being one of the constituent bodies for the time being of the General Council, and being in the opinion of the General Council of sufficient importance to be worthy of such a privilege, the power of returning a member to the General Council, either separately or collectively with any other body or bodies in the same part of the United Kingdom capable of granting a medical diploma; (*b*) that it is expedient to confer on any constituent body, for the time being returning a member to the General Council collectively with any other body or bodies, and being in the opinion of the General Council of sufficient importance to be worthy of such a privilege, the power of returning a member to such council separately; (*c*) that it is expedient to confer on the registered medical practitioners resident in any part of the United Kingdom the power of returning an additional member to the General Council; (*d*) that it is expedient that any constituent body, having in the opinion of the General Council so diminished in importance as not to be entitled to such privilege, should either be wholly deprived of the power of returning a member to the General Council, or be deprived of the power of returning a member separately, and permitted to return a member collectively with some other body or bodies.—(2) The Privy Council, before considering such representation, shall cause the same to be laid before both Houses of Parliament.—(3) If either House of Parliament within forty days (exclusive of any period of adjournment for more than one week) next after any such representation has been laid before such House present an address to Her Majesty declaring that such representation or any part thereof ought not to be carried into effect, no further proceedings shall be taken in respect of the representation in regard to which such address has been presented, but if no such address is presented by either House of Parliament within such forty days as aforesaid the Privy Council may, if they think fit, report to Her Majesty that it is expedient to give effect to such representation, and it shall be lawful for Her Majesty, by Order in Council, to give effect to the same, and any Order in Council so made shall be of the same validity as if it had been enacted in this Act.

PART II.—COLONIAL AND FOREIGN PRACTITIONERS.

XI. *Registration of colonial practitioner with recognised diploma.*—On and after the prescribed day where a person shows to the satisfaction of the registrar of the General Council that he holds some recognised colonial medical diploma or diplomas (as hereinafter defined) granted to him in a British possession to which this Act applies, and that he is of good character, and that he is by law entitled to practise medicine, surgery, and midwifery in such British possession, he shall, on application to the said registrar, and on payment of such fee not exceeding five pounds, as the General Council may from time to time determine, be entitled, without examination in the United Kingdom, to be registered as a colonial practitioner in the Medical Register; provided that he proves to the satisfaction of the registrar any of the following circumstances:—(1) That the said diploma or diplomas was or were granted to him at a time when he was not domiciled in the United Kingdom, or in the course of a period of not less than five years during the whole of which he resided out of the United Kingdom; or (2) that he was practising medicine or surgery or a branch of medicine or surgery in the United Kingdom on the said prescribed day, and that he has continuously practised the same either in the United Kingdom or elsewhere for a period of not less than ten years immediately preceding the said prescribed day.

XII. *Registration of foreign practitioner with recognised diploma.*—On and after the said prescribed day where a person shows to the satisfaction of the registrar of the General Council that he holds some recognised foreign medical diploma or diplomas (as hereinafter defined) granted in a foreign country to which this Act applies, and that he is of good character, and that he is by law entitled to practise medicine, surgery, and midwifery in such foreign country, he shall, on application to the said registrar, and on payment of such fee not exceeding five pounds, as the General Council may from time to time determine, be entitled, without examination in the United Kingdom, to be registered as a foreign practitioner in the Medical Register; provided that he proves to the satisfaction of the registrar any of the following circumstances:—(1) That he is not a British subject; or (2) that, being a British subject, the said diploma or diplomas was or were granted to him at a time when he was not domiciled in the United Kingdom, or in the course of a period of not less than five years during the whole of which he resided out of the United Kingdom; or (3) that, being a British subject, he was practising medicine or surgery, or a branch of medicine or surgery, in the United Kingdom on the said prescribed day, and that he has continuously practised the same in the United Kingdom or elsewhere for a period of not less than ten years immediately preceding the said prescribed day.

XIII. *Medical diploma of colonial and foreign practitioner when deemed to be recognised.*—(1) The medical diploma or diplomas granted in a British possession or foreign country to which this Act applies, which is or are to be deemed such recognised colonial or foreign medical diploma or diplomas as is or are required for the purposes of this Act, shall be such medical diploma or diplomas as may be recognised for the time being by the General Council as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery. (2) Where the General Council have refused to recognise as aforesaid any colonial or foreign medical diploma, the Privy Council, on application being made to them, may, if they think fit, after considering such application, and after communication with the General Council, order the General Council to recognise the said diploma, and such order shall be duly obeyed. (3) If a person is refused registration as a colonial or foreign practitioner on any other ground than that the medical diploma or diplomas held by such person is or are not such recognised medical diploma or diplomas as above defined, the registrar of the General Council shall, if required, state in writing the reason for such refusal, and the person so refused registration may appeal to the Privy Council, and the Privy Council, after communication with the General Council, may dismiss the appeal, or may order the General Council to enter the name of the appellant on the Register. (4) A person may, if so entitled under this Act, be registered both as a colonial and a foreign practitioner.

XIV. *Separate list of colonial and foreign practitioners in Medical Register.*—The Medical Register shall contain a separate list of the names and addresses of the colonial practitioners, and also a separate list of the names and addresses of the foreign practitioners registered under this Act; each list shall be made out alphabetically according to the surnames; and the provisions of the Medical Act, 1858, relating to persons registered under that Act, and relating to the Medical Register and to offences in respect thereof, shall, so far as may be, apply in the case of colonial and foreign practitioners registered under this Act and of the said lists of those practitioners, in the same way as such provisions apply in the case of persons registered under the said Medical Act, 1858, and of the Register as kept under that Act.

XV. *Medical titles of colonial and foreign practitioners.*—On and after the appointed day it shall be lawful for any registered medical practitioner who, being on the list of colonial or of foreign practitioners, is on that day in possession of or thereafter obtains any recognised colonial or foreign medical diploma granted in a British possession or foreign country to which this Act applies to cause a description of such diploma to be added to his name in the Medical Register.

XVI. *Registration of foreign degrees held by registered medical practitioners.*—On and after the appointed day it shall be lawful for any registered medical practitioner who, being on the Medical Register by virtue of English, Scotch, or Irish qualifications, is in possession of a foreign degree in medicine, to cause a description of such foreign medical degree to be added to his name as an additional title in the Medical Register, provided he shall satisfy the General Council that he obtained such degree after proper examination and prior to the passing of this Act.

XVII. *Power of Her Majesty in Council to define colonies and foreign countries to which this part of the Act applies.*—(1) Her Majesty may from time to time by Order in Council declare that this part of this Act shall be deemed on and after a day to be named in such Order to apply to any British possession or foreign country which in the opinion of Her Majesty affords to the registered medical practitioners of the United Kingdom such privileges of practising in the said British possession or foreign country as to Her Majesty may seem just; and from and after the day named in such Order in Council such British possession or foreign country shall be deemed to be a British possession or foreign country to which this Act applies within the meaning of this part thereof; but until such Order in Council has been made in respect of any British possession or foreign country, this part of this Act shall not be deemed to apply to any such possession or country; and the expression "the prescribed day" as used in this part of this Act means, as respects any British possession or foreign country, the day on and after which this part of this Act is declared by Order in Council to apply to such British possession or foreign country. (2) Her Majesty may from time to time by Order in Council revoke and renew any Order made in pursuance of this section; and on the revocation of such Order as respects any British possession or foreign country, such possession or foreign country shall cease to be a possession or country to which this part of this Act applies, without prejudice nevertheless to the right of any persons whose names have been already entered on the Register.

XVIII. *Amendment of 21 & 22 Vict., c. 90, s. 36, as to medical officers in ships.*—Nothing in the Medical Act, 1858, shall prevent a person holding a medical diploma entitling him to practise medicine or surgery in a British possession to which this Act applies from holding an appointment as a medical officer in any vessel registered in that possession.

PART III.—MISCELLANEOUS PROVISIONS.

XIX. *Default of General Council.*—If at any time it appears to the Privy Council that the General Council has failed to secure the maintenance of a sufficient standard of proficiency at any qualifying examinations, or that occasion has arisen for the General Council to appoint assistant examiners under this Act for the purpose of examinations held by any medical corporation, or to exercise any power or perform any duty, or do any act or thing vested in or imposed on or authorised to be done by the General Council under the Medical Acts or this Act, the Privy Council may notify their opinion to the General Council; and if the General Council fail to comply with any directions of the Privy Council relating to such notification, the Privy Council may themselves give effect to such directions, and for that purpose may exercise any power, or do any act or thing vested in or authorised to be done by the General Council, and may of their own motion do any act or thing which, under the Medical Acts or this Act, they are authorised to do in pursuance of a representation or suggestion from the General Council.

XX. *Addition to qualifications under 21 & 22 Vict., c. 90.*—The diploma of member of the King and Queen's College of Physicians in Ireland, and the degree of Master in Obstetrics of any university in the United Kingdom, shall be deemed to be added to the qualifications described in Schedule A to the Medical Act, 1858.

XXI. *Registration of diploma in sanitary science.*—Every registered medical practitioner to whom a diploma for proficiency in sanitary science, public health, or State medicine, has after special examination been granted by any college or faculty of physicians or surgeons or university in the United Kingdom, or by any such bodies acting in combination, shall, if such diploma appears to the Privy Council or to the General Council to deserve recognition in the Medical Register, be entitled, on payment of such fee as the General Council may appoint, to have such diploma entered in the said Register, in addition to any other diploma or diplomas in respect of which he is registered.

XXII. *Exercise of powers of Privy Council.*—(1) All powers vested in the Privy Council by the Medical Acts or this Act may be exercised by any two or more of the Lords and others of Her Majesty's most honourable Privy Council. (2) Any act of the Privy Council under the Medical Acts or this Act shall be sufficiently signified by an instrument signed by the clerk of the Council, and every order and act signified by an instrument purporting to be signed by the clerk of the Council, shall be deemed to have been duly made and done by the Privy Council, and every instrument so signed shall be received in evidence in all courts and proceedings without proof of the authority or signature of the clerk of the Council, or other proof.

XXIII. *Evidence of orders.*—The following copies of any orders made in pursuance of the Medical Acts or this Act, or the Dentists Act, 1878, shall be evidence—that is to say:—(1) Any copy purporting to be printed by the Queen's printer, or by any other printer in pursuance of an authority given by the General Council. (2) Any copy of an order certified to be a true copy by the registrar of the General Council, or by any other person appointed by the General Council either in addition to or in exclusion of the registrar to certify such orders.

SAVING CLAUSES.

XXIV. *Saving as to practice of existing practitioners.*—This Act shall not increase or diminish the privileges in respect of his practice of any person who, on the day preceding the appointed day, is a registered medical practitioner, and such person shall be entitled on and after the said appointed day to practise, in pursuance of the qualification possessed by him before the said appointed day, in medicine, surgery, and midwifery, or any of them, or any branch of medicine or surgery, according as he was entitled to practise the same before the said appointed day, but not further or otherwise.

XXV. *Saving as to local law.*—Any person who at the time of the repeal of any enactment repealed by this Act was, in pursuance of such enactment, legally entitled to practise as a qualified practitioner in any colony or part of Her Majesty's dominions other than the United Kingdom, shall after the date of such repeal continue to be so entitled if he would have been entitled if no such repeal had taken place.

DENTISTS.

XXVI. *Provisions as to 41 & 42 Vic., c. 33.*—It is hereby declared that the words "title addition, or description," where used in the Dentists Act, 1878, include any title, addition to a name, designation or description, whether expressed in words or by letters, or partly in one way and partly in the other. There shall be repealed so much of Section 4 of the Dentists Act, 1878, as provides that a prosecution for any of the offences above in that Act mentioned shall not be instituted by a private person, except with the consent of the General Council or of a branch council, and a prosecution for any such offences may be instituted by a private person accordingly. Notwithstanding anything in Section 5 of the Dentists Act, 1878, the rights of any person registered under the Dentists Act, 1878, to practise dentistry or dental surgery in any part of Her Majesty's dominions other than the United Kingdom shall be subject to any local law in force in that part. It shall be lawful for Her Majesty at any time after the said appointed day to declare by Order in Council that Section 29 of the said Dentists Act, 1878, shall be in force on and after a day to be named in such Order, but in the meantime and until such order has been made, and before such day as last aforesaid, such section shall not be deemed to be in force. Save as in this Act mentioned the Dentists Act, 1878, shall not be affected by this Act.

DEFINITIONS.

XXVII.—In this Act, unless the context otherwise requires, the expression "part of the United Kingdom" means, according to circumstances, England, Scotland, or Ireland. The expression "British possession" means any part of Her Majesty's dominions exclusive of the United Kingdom, but inclusive of the Isle of Man and the Channel Islands; and where parts of such dominions are under both a central and a local legislature, all parts under one central legislature are for the purposes of this definition deemed to be one British possession. The expression "local law" means an Act or Ordinance passed by the legislature of a British possession. The expression "the appointed day" means the first of June, one thousand eight hundred and eighty-seven, or such other day in June, one thousand eight hundred and eighty-seven, as may be appointed by the Privy Council. The expression "medical corporation" means any body in the United Kingdom, other than a university, for the time being competent to grant a diploma or diplomas conferring on the holder thereof, if he has passed a qualifying examination, the right of registration under the Medical Acts. The expression "registered medical practitioner" means any person for the time being registered under the Medical Acts. The word "diploma" means any diploma, degree, fellowship, membership, licence, authority to practise, letters testimonial, certificate, or other status or document granted by any university, corporation, college, or other body, or by any departments of or persons acting under the authority of the government of any country or place within or without Her Majesty's dominions. The expression "medical diploma" means a diploma granted in respect of medicine, surgery, and midwifery, or any of them, or any branch of medicine or surgery. The word "person" includes a body of persons, corporate or not corporate. The expression "the Medical Acts" means the Medical Act, 1858 (21 & 22 Vict., c. 90), and any Acts amending the same passed before the passing of this Act.

REPEAL.

Repeal of enactments in schedule.—XXVIII. The Acts mentioned in the first part of the schedule to this Act are hereby repealed to the extent mentioned in the third column of the said part; and the Acts mentioned in the second part of the said schedule shall be repealed on and after the appointed day to the extent mentioned in the third column of the said last mentioned part; provided that the repeal enacted by this section shall not affect anything done or suffered, or any right or title acquired or accrued, before such repeal takes effect, or any remedy, penalty, or proceeding in respect thereof.

THE SCHEDULE.

FIRST PART.

Session and chapter.	Title or short title of Act.	Extent of repeal.
21 & 22 Vict. c. 90	The Medical Act, 1858	Sections 4 and 5. In Section 6 the words "The President shall be a Member of all the Branch Councils." Section 24.
46 & 47 Vict. c. 19	The Medical Act (1858) Amendment Act, 1883	The whole Act.

SECOND PART.

21 & 22 Vict. c. 90	The Medical Act, 1858	Section 31.
31 & 32 Vict. c. 29	The Medical Act Amendment Act, 1868	The whole Act.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6132 births and 2957 deaths were registered during the week ending June 26th. The annual death-rate in these towns, which had declined in the preceding fourteen weeks from 29·3 to 16·8, rose again last week to 17·0. During the first twelve weeks of the current quarter the death-rate in these towns averaged only 18·7 per 1000, and was 3·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 12·4 in Cardiff, 12·6 in Brighton, 12·9 in Sheffield, and 13·6 in Norwich. The rates in the other towns ranged upwards to 23·7 in Portsmouth, 24·5 in Salford, 24·9 in Bolton, and 37·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 265 and 293 in the preceding two weeks, further rose last week to

312; they included 96 from measles, 83 from diarrhœa, 56 from whooping-cough, 32 from "fever" (principally enteric), 24 from scarlet fever, 21 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Halifax, whereas they caused the highest death-rates in Bolton, Portsmouth, and Preston. The greatest mortality from measles occurred in Portsmouth, Bolton, and Preston; from whooping-cough in Manchester and Preston; from "fever" in Portsmouth; and from diarrhœa in Derby and Salford. The 21 deaths from diphtheria in the twenty-eight towns included 14 in London, 2 in Wolverhampton, and 2 in Birmingham. Small-pox caused no death either in London and its outer ring, or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had been 31 and 23 on the preceding two Saturdays, had further declined to 17 at the end of last week; 4 cases were admitted to these hospitals during the week, against 9 and 2 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 216 and 184 in the preceding two weeks, rose again last week to 194, but were 29 below the corrected average. The causes of 73, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Leicester, Sunderland, Newcastle-upon-Tyne, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Oldham, Huddersfield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·9 and 21·7 per 1000 in the preceding two weeks, declined to 20·2 in the week ending June 26th; this rate exceeded, however, by 3·2 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 12·5 and 16·4 in Greenock and Perth, to 20·8 in Edinburgh and 22·5 in Glasgow. The 498 deaths in the eight towns showed a decline of 38 from the number in the previous week, and included 21 which were referred to whooping-cough, 20 to measles, 11 to diarrhœa, 7 to scarlet fever, 6 to "fever," and not one either to diphtheria or small-pox; in all, 65 deaths resulted from these principal zymotic diseases, against 68, 49, and 57 in the preceding three weeks. These 65 deaths were equal to an annual rate of 2·6 per 1000, which exceeded by 0·8 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 21, 19, and 18 in the previous three weeks, rose again last week to 21, of which 16 occurred in Glasgow, 3 in Aberdeen, and 2 in Edinburgh. The 20 deaths from measles showed a further increase upon recent weekly numbers, and included 11 in Edinburgh, 6 in Leith, and 3 in Glasgow. The 11 deaths attributed to diarrhœa also exceeded the numbers in recent weeks, and were 5 above the number in the corresponding week of last year. Six of the 7 fatal cases of scarlet fever and 5 of the 6 deaths referred to "fever" occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 90 and 93 in each of the previous two weeks, declined last week to 86, but exceeded by 12 the number in the corresponding week of last year. The causes of 82, or 16 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 20·8 and 22·9 per 1000 in the preceding two weeks, further rose to 24·7 in the week ending June 26th. During the first twelve weeks of the current quarter the death-rate in the city averaged 25·8 per 1000; the mean rate during the same period did not exceed 17·3 in London and 19·7 in Edinburgh. The 167 deaths in Dublin last week showed a further increase of 12 upon the numbers in the two previous weeks, and included 10 which were referred to the principal zymotic diseases, against 5 and 7 in the previous two weeks; 3 resulted from scarlet fever, 3 from whooping-cough, 2 from "fever," 1 from diphtheria, 1 from diarrhœa, and not one either from small-pox or measles. These 10 deaths were equal to an annual rate of 1·5 per 1000, the rates from the same diseases being 1·8 in London and 3·7 in Edinburgh. The fatal cases both of scarlet fever and whooping-cough showed an increase upon the numbers in the previous week. The deaths referred to fever were fewer by one than the number in the previous week, the mortality from this disease having shown a marked decline during the present quarter. Five inquest cases and 6 deaths from violence were registered; and 49, or more than a quarter, of the deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed an increase upon recent weekly numbers. The causes of 28, or 17 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

JOHN HUNTER.

To the Editor of THE LANCET.

SIR,—Circumstances have brought teaching in hospitals as well as John Hunter rather to the fore lately. I have in my possession the correspondence that took place between him and his colleagues at St. George's Hospital, relating to their unfortunate disagreement at the hospital. I send you some extracts from an address by Hunter to the governors of the hospital. I have omitted some portions that are more personal than at the present time interesting. At the time (1768) of his election as surgeon to the hospital, his colleagues were Cæsar Hawkins, Bromfield, and Gunning; subsequently Charles Hawkins, George Hawkins, William Walker, and Thomas Keate, with Everard Home as an assistant. I do not now offer any opinion upon this unfortunate controversy—the immediate cause of his death,—as I may print the whole correspondence; it shows well the state of medical education not only at St. George's a hundred years ago, but also at Guy's and St. Thomas's Hospitals, the information being supplied by the teachers at these hospitals at that time for the guidance of the staff at St. George's in drawing up a system for medical education. I am, Sir, yours truly,

June 12th, 1886. CHARLES HAWKINS.

"To the Governors of St. George's Hospital.

"When I solicited to be appointed one of the surgeons to St. George's Hospital, it was not with a view to augment my income, either immediately by the profits of the hospital, or in a secondary way by increasing my practice; but to acquire opportunities of extending my knowledge, that I might be more useful to mankind, not only by improving my private practice, but if I should be enabled to make discoveries even in the art itself. I had a view also to the instruction of those who were studying under me, particularly to that of the pupils of the hospital, whose improvement is one principal benefit accruing to the public from such instructions, and I have reason to believe that my intentions and endeavours in all these points have been attended with some success. . . . I conceived that the governors of the hospital would wish that not only immediate relief should be given to the poor and distressed, but that the hospital should diffuse its influence to mankind in general; and by these means, even to themselves. I concluded that to render the hospital of such universal use would be agreeable to the feelings of the governors of this charity, and probably considered by them as the most important service. I conceived to give an hospital a reputation for improvement it was to invite the philosopher as well as the charitable to contribute to its support. Other hospitals were beginning to participate in the improving spirit of the times, more especially those into which the younger surgeons had been elected. They united their powers, and had lectures given to their pupils, not only in surgery, but in every branch of the healing art. Mr. Pott, though one of the senior surgeons in London, gave lectures to the pupils of St. Bartholomew's Hospital, which lectures became the basis of his works on the operations in surgery, and do credit to the governors of that charity for their choice of one so able to instruct.....Finding the pupils of St. George's Hospital fewer than they had formerly been, I imputed it to the want of that increasing attention which the surrounding improvements in the art required, for one part should keep pace with the other. My practice in the hospital soon convinced me that this observation was just, and having been long in

the habit of improving myself along with others, it had become in a manner natural to me.....When I mentioned what the medical gentlemen of other hospitals did, and what I thought we should do, one gentleman said, 'he did not choose to lose any reputation he might have in surgery by giving lectures,' which, at least, was modest. Talking of the improvement of the art, one of the surgeons confessed 'he did not see where the art could be improved.' The natural conclusion from this declaration was that such a man would never improve it; but the answer then made was, 'to see where anything could be improved might be considered as going almost half way towards the improvement itself; and that Lord Bacon was the cause of all the advances in philosophy since his day, by seeing and pointing out where and how they might be made.'.....In this [a recent election of a surgeon to the hospital], as in most other public contests, the mind, inflamed by opposition, lost sight of the great object, by which means private friendships and connections had more weight than public utility, to which object the governors will not on the present occasion confine themselves. My motive was in the first place to serve the hospital, and in the second to diffuse the knowledge of the art, that all might be partakers of it; this, indeed, is the highest office in which a surgeon can be employed, for when considered as a man qualified only to dress a sore or perform a common operation, and perhaps not all of those that may be reckoned common, he cannot be esteemed an ornament to his profession. ..... They [the governors] will consider how far a numerous class of pupils increases the reputation of the hospital; they will consider whether those numbers do not produce the secondary good arising from an hospital, which is the effectual diffusion of knowledge, and, if so, whether every surgeon should not be in duty bound to contribute his share towards this good purpose ..... I hope this Court will not consider this as similar to a contested election between two men. It is of general interest; it concerns no individual, or, if any, only four men, who are servants of the hospital; and though in one point of view I may appear to stand single, yet I stand on equal ground with the governors of this charity, who formerly established the very law the advantages of which I have now illustrated. Indeed, from a consciousness of the disinterestedness of my motives, and a conviction of the clearness of the question in point of public utility, which I trust they cannot overlook and will not disregard, it would give me more pleasure to see the friends of the other gentlemen here to-day than my own. In whatever way it may be determined to me is personally immaterial; the good of mankind, the improvement of the healing art, and the character of the hospital are the motives of my conduct, and according to which, whatever may be the decision of the present question, I shall continue to do my duty to the hospital as a charity, and confine myself to the laws of the institution.

"Leicester square, Feb. 28th, 1793." "JOHN HUNTER.

PROPOSED UNIFORM DIETARY SCALES FOR WORKHOUSES AND INFIRMARIES.

To the Editor of THE LANCET.

SIR,—At a meeting of the guardians of St. George-in-the-East on Friday last, Mr. Dellow moved a resolution to the effect that a memorial be addressed to the Local Government Board, asking them to adopt a uniform dietary scale for all the workhouses in the metropolis. He had statistics for 1883 showing the annual cost per head for provisions in the various metropolitan workhouses, and from these it appears that the cost at Whitechapel is the lowest, being £5 19s. 3d. per head per annum, while at Lewisham it is £12 1s. 9d. Referring to the East-end, he showed that the cost of provisions was the highest at St. George's, where it is £7 11s. 9d., or £1 12s. 6d. more than at Whitechapel Union. Poplar, Stepney, Shoreditch, and Hackney each cost varying amounts between the two given above, but increasing in the order in which they are named. The motion was seconded and carried with but two dissentients. Mr. Crowder gave notice that he would move an addition to the resolution asking for a uniform dietary scale in all metropolitan Poor-law institutions.

There is no doubt that there should be uniform dietary scales for the inmates of all workhouses and infirmaries, and in addition there should be drawn up uniform diet tables for all the officers and servants residing in these institutions. As it is, there is much discrepancy in the dietaries and no real reason for it, as the duties and responsibilities of the officers and servants are much the same in all. Why, for instance, should the assistant medical officer at Marylebone Infirmary have a much better dietary than the assistant medical officer at St. George-in-the-East? At Whitechapel Infirmary, the assistant medical officer has extra salary and provides his own rations. If the Local Government Board were to effect these changes, they would remove the existing dissatisfaction. Uniformity, however, could only be obtained on paper, for what according to the diet table may appear to be a very good dietary, may in reality be but a poor one, as, though the articles are supplied in proper quantity, some of them may be so deficient in quality as to be scarcely fit for food. As there is frequently a considerable amount of trickery in the supplying public institutions with provisions &c., it behoves guardians to be on the alert, and see for themselves that contractors continue to supply goods of the same quality as the samples. A more frequent visitation of the stores and at unexpected times, or an inspection when goods are being delivered, would in all probability be attended with the most beneficial results.

I am, Sir, your obedient servant,

London, June 21st, 1886. SCRUTATOR.

DURATION OF LIFE OF THE RED BLOOD-CORPUSCLES.

To the Editor of THE LANCET.

SIR,—In referring to a paper on "The Duration of Life of the Red Blood-corpuscles, as ascertainable by Transfusion," recently read by me before the Royal Society of Edinburgh, your correspondent in your last issue ascribed to me a method of investigation which would entirely deprive the results of any value which may attach to them.

So far from transfusing the blood of one animal into the circulation of another of different species, whose blood-corpuscles were of different size and shape, I was at pains to show that such a method of investigation, implying as it did the use of "dissimilar" blood, was absolutely worthless for the attainment of the object in view, since the blood-corpuscles of such blood always break down in the body of their host within a day or two of injection, and hence their duration of life could offer no criterion of that of the normal red blood-corpuscles. In all my experiments, therefore, the blood used was that obtained from an animal of the same species -so-called "similar" blood --the fate of which after transfusion differs essentially from that of dissimilar blood, but resembles in all respects that of the normal blood.

I should feel greatly obliged if you could kindly give the same prominence to the above correction as was given to the original reference, as the ignorance on my part implied in the use of the kind of blood described by your correspondent for arriving at any conclusions regarding the life duration of normal blood-corpuscles is so great as would serve to completely condemn the accuracy of my results in the estimation of all who are already acquainted with the subject of transfusion. I remain, Sir, yours faithfully,

Edinburgh, June 27th, 1886. WILLIAM HUNTER.

BRITISH MEDICAL BENEVOLENT FUND JUBILEE.

To the Editor of THE LANCET.

SIR,—In addition to the sums already mentioned, the following donations have been received:—

	£	s.		£	s.
W. Cadge, Esq. (Norwich)	52	10	W. Morrant Baker, Esq. ...	10	10
G. D. Pollock, Esq.	21	0	Sir William Mac Cormac ...	5	5
Sir Spencer Wells	21	0	W. Berkeley Hill, Esq.	5	5
Sir Henry Thompson	21	0	D. de Berdt Hovell, Esq. ...	5	5
Lady Wilson	21	0	F. E. Webb, Esq.	5	5
Mrs. Montefiore	21	0	C. E. Atkin, Esq.	5	5
Dr. Wegg	21	0	C. A. Atkin, Esq.	5	5
E. Parker Young, Esq.	21	0	Dr. Withers Moore	5	5
Dr. Ord	20	0	Mrs. Franz (through Dr. Parsons) (Dover)	5	0
Dr. Brodie Sewell	10	10			

Mr. Veasey's donation is £25, instead of £20, as previously stated.

The list of guests at the banquet must be closed almost at once, and I have to request that all who have not replied will do so without delay.

I am, Sir, yours faithfully,

34, Seymour-street, Portman-square, W. W. H. BROADBENT.

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY ELECTION.

THE election of a representative in Parliament of the Universities of Edinburgh and St. Andrews will take place next week. Mr. Macdonald, the present member, has issued an address to the electors in which he offers himself for re-election; and at present it seems most unlikely that any opposition will be offered to his return. In consequence of the absence of the Vice-Chancellor of the University the duties of returning officer for the election will devolve upon Professor Sir Douglas Maclagan, the senior professor available, who at a recent meeting of the University Court was deputed by their authority to act for the time, and for the purpose referred to, as Vice-Chancellor of the University. The present member, the Right Hon. J. H. A. Macdonald, Q.C., was returned for the University at the last general election by a considerable majority of votes over Mr. Erichsen; he acted as Lord-Advocate under the late Conservative Government.

SIR DOUGLAS MACLAGAN.

Last Wednesday a congratulatory address was presented to Professor Sir Douglas Maclagan, on the occasion of his knighthood, by the undergraduates of the University, through the Students' Representative Council. Sir William Turner presided at the meeting, which was held in the anatomy theatre, and which was attended by a densely packed crowd of enthusiastic students. In replying to the address, and in thanking the students for their enthusiastic demonstration in his honour, Professor Maclagan took occasion to discuss the claims of wide culture in relation to medical studies; and he urged upon his hearers the importance of keeping their minds free from the narrowing effect of too close concentration upon one branch of study. He advocated the cultivation of collateral interests in art or literature, and, above all, the maintenance of a robust and healthy physique by developing an interest in one or other of the forms of physical exercise or of manly sports.

DR. WENDELL HOLMES IN EDINBURGH.

Dr. Holmes's visit to Edinburgh has partaken largely of the nature of an academic triumph, and not only has he been most warmly welcomed by all connected with the University, but his presence in the city has excited great interest amongst the very many who, as members of the reading community, have come in contact with his writings. On Friday afternoon the honorary degree of LL.D. was conferred upon him in the Upper Library Hall of the University by the Chancellor, Lord Inglis. The hall was crowded for the occasion, there being a large number of ladies present in reserved seats and in the galleries, whilst the body of the hall was occupied by visitors and a considerable number of students. On entering the hall Dr. Holmes was greeted with enthusiastic cheering, which was from time to time renewed as the ceremony proceeded. Professor Kirkpatrick, Dean of the Faculty of Law, delivered a short address of the customary nature, in presenting Dr. Holmes to the Chancellor for promotion to the degree. He shortly referred to the leading events in Dr. Holmes's career, and enumerated the names of some of his best-known writings. After Lord Inglis had completed the ceremony of "capping" the Autocrat, the latter signed the roll-book of honorary graduates of the University, and then, in response to urgent cries of "speech," he addressed a few words to the students, thanking them for the warm reception they had accorded him, and expressing the gratification he had experienced in enacting his part in that day's ceremony. The meeting terminated amidst renewed cheers for Dr. Holmes and the singing of "For he's a jolly good fellow." On Saturday evening the students held a concert in honour of Dr. Holmes, at which he was present. Professor Crum Brown occupied the chair, and the Queen-street Hall, which was taken for the occasion, was crowded with an interested audience of students and their friends. After the first part of the programme had been concluded, Dr. Holmes was presented with an address from the students welcoming his visit to Edinburgh, and expressing their earnest appreciation of the value of his writings. In replying, Dr. Holmes sketched an interesting outline of his own career, and in particular he dwelt upon the relation which existed between the literary and professional portions of his life-work. In this connexion he gave important advice to young men who have a passion for literary labours. Literature, he said, was a good staff for walking with, but not a good one to lean upon. He had early received an important piece of advice from the lips of Coleridge, that every literary man should have as well some fixed and regular occupation; this advice he handed on to any who might feel tempted to exchange steady preparation for a practical career for the uncertain pathway of a literary life. In concluding his remarks, Dr. Holmes thanked the students for the brilliant reception they had given him, the memory of which would be a lasting and inspiring pleasure to him for the remainder of his life.

Edinburgh, June 29th.

ABERDEEN.

(From our own Correspondent.)

ROYAL INFIRMARY.

THE preface to the annual report for last year says that "the history of the Aberdeen Royal Infirmary during 1885, apart from the stated work of the hospital, has been marked by some features of interest. ..... The managers record with satisfaction that the appointment of Miss Lumsden has already been attended with the best results, both in the arrangements for nursing and housekeeping. ..... The sanitary condition of the hospital has been greatly improved; but the administration is put to disadvantage on account of the small size of some of the wards and deficiency of accommodation; attempts at improvement have been made, but nothing effectual can be done without improved buildings." The number of cases treated in the wards was 1951, and of these 1135 were surgical, with 29 deaths; 816 were medical, with 85 deaths; 910 persons, including 194 eye cases, received advice and medicine as out-patients. The expenditure for the year was £7171 5s. 1d., and unfortunately the income fell short of this sum by £956 3s. 2d. The most important changes proposed in the new charter are: 1. The separation of the management of the Lunatic Asylum from that of the Infirmary and Convalescent Hospital. 2. The present Board of Managers is hereafter to be known as the Constituent Board, which is to meet annually (instead of quarterly as at present), to elect directors for the government of each branch of the institution. The number of directors on each of the two boards was first fixed at fifteen, but as the two committees might occasionally have to meet together, it was thought better to fix the number at nine. 3. Ladies are "to be as free as men are to take part in the management" of the institution. The Charter Committee suggest that the contemplated changes in the constitution should be carried out by means of an Act of Parliament, in place of by new charter, which involves the use of cumbrous and not readily intelligible language, whereas in an Act of Parliament the phraseology might be made much clearer, and the new constitution placed in a much more distinct light before all concerned. At their quarterly meeting, held on the 14th ult., the managers agreed to the recommendation of the Committee of Management that an assistant-physician should be appointed, and resolved to make the appointment at their next meeting in September. Five candidates entered the field, but one, Dr. Edmond, is said to have retired, the four remaining being Drs. Booth, MacGregor, Rodger, and Smith. It is to be hoped that the gentleman appointed will do something to supply the want of clinical teaching.

AMPUTATION OF UPPER LIMB, INCLUDING SCAPULA AND TWO-THIRDS OF CLAVICLE.

At the beginning of the winter session, Professor Ogston excised, in the case of a young man aged twenty-one, the head of the humerus, which was involved in a large sarcomatous tumour. The disease returned, and to eradicate it thoroughly Dr. Ogston removed the entire limb, including the scapula and two-thirds of the clavicle. The patient made an excellent recovery.

DEATH OF DR. OGILVIE FORBES.

Dr. Ogilvie Forbes, who till 1877 filled the chair of Physiology in Aberdeen, died at Boyndlie, near Fraserburgh, on the 25th ult. The son of a physician, he chose his father's profession, and was first engaged in private practice; but in

1848 he was appointed Lecturer on Physiology in Marischal College, and then retired from practice. On the amalgamation of the two colleges he was appointed Professor of the Institutes of Medicine, which, owing to failing health, he resigned in 1877, when Dr. Stirling was appointed his successor. Dr. Ogilvie Forbes was sixty-six years of age.

DISEASED MEAT PROSECUTION.

There have recently been several prosecutions of individuals for selling diseased meat, and the medical evidence has in each been very conflicting. On Saturday of last week the sanitary inspector presented a petition to the magistrates craving permission to destroy a certain quantity of ham which he found being sold for human food, and which, in his opinion, was unfit for such. Dr. Thomson, medical officer of health, said that "the hams were altered in colour, smell, and consistency—the worst parts were putrid." A medical witness for the defence said that the ham "was all one piece; it had a very nice colour and a very sweet smell, with the exception of one part." The magistrates, however, declared the ham unfit for human food, and ordered it to be destroyed. Some weeks ago the sanitary officials seized a large quantity of fish which they considered unfit for human food. Drs. Beveridge and MacGregor said on oath that they were of the same opinion, but medical witnesses for the defence said they considered the fish quite good and fit for human food, and, indeed, had some of the worst cooked and ate them. Again, however, the verdict was in favour of the prosecution.

Aberdeen, June 29th.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At a meeting of medical students connected with the medical school of the college, held last week, the following resolutions were unanimously adopted:—1. "Whereas medical students who have entered under the new regulations, made in 1882, are subjected to other rules subsequently introduced, to this the meeting does object on the grounds that due notice has not been given." 2. "Whereas the fees formerly paid for re-examination have been afterwards (1886) increased without any apparent justification, the meeting is of opinion that the Council of the Royal College of Surgeons should reconsider their decision." The composition of these resolutions is not so well put as it might be, but the last paragraph has reference to the present fee for re-examination, which, early this year, was raised to three guineas instead of two, as formerly. At the examinations for the First Half, which commenced last week, the failures were unusually numerous—viz, of nineteen candidates, fifteen were rejected.

UNIVERSITY OF DUBLIN.

The annual meeting of the Senate took place last week, and among the graces submitted from the Provost and Senior Fellows was that the degree of LL.D. (*honoris causâ*), should be conferred on John Tyndall, F.R.S., Professor of Natural Philosophy in the Royal Institution of Great Britain. Dr. Ingram said that he asked the votes of the Senate in favour of a distinguished Irishman, Professor John Tyndall. He stood in the foremost rank of living physicists, and there was scarcely any branch of physics with which his name is not honourably associated. Heat considered as a mode of motion, the absorption and radiation of gases and vapours, the phenomena of diamagnetism, and the relations of magnetism and diamagnetism to molecular structure, the floating matter of the air in relation to putrefaction and infection, the motion of glaciers, the methods of lighthouse illumination, and the theory of sound—all these subjects had been investigated by him. He was a master of the art of scientific exposition, as might be seen in his accounts of Faraday as a discoverer, and of Pasteur's researches on spontaneous generation; and as a writer he possessed a vigour, elasticity, and occasional elevation of style which many men of letters might well envy. The grace was passed.

THE ADELAIDE HOSPITAL, DUBLIN.

The examinations for the Hudson Scholarship, which consists of a gold medal and £30, and the Hudson Prize—a silver medal and £10—have concluded. There were two competitors, but the answering being below the standard fixed, the scholarship will not be awarded this year. Mr. Strangman, a fourth-year student, obtained the Hudson Prize.

BELFAST ROYAL HOSPITAL.

A handsome stained glass window has been placed on the main staircase of this hospital, which has been erected at the sole expense of Dr. Whitla, author of the well-known "Manual of Materia Medica," and one of the visiting physicians of the institution.

Dublin, June 29th.

THE COLLEGE ELECTION.

THE voting at the above election, which took place at the Royal College of Surgeons on Thursday afternoon, was not of that exciting character which often signalises this event. Only about 260 Fellows voted, and at five o'clock the result, which is as follows, was announced:—

MR. EDWARD LUND	162	including	1 plumper.
MR. BERKELEY HILL	142	„	10 „
MR. REGINALD HARRISON	109	„	10 „
MR. SEPTIMUS SIBLEY	108	„	3 „
Mr. Alfred Willett	96	„	10 „
Mr. John Couper	80	„	6 „
Mr. R. Brudenell Carter	71	„	5 „
Mr. James Rouse	34	„	1 „

Mr. Edward Lund and Mr. Berkeley Hill were therefore duly re-elected, and Mr. Reginald Harrison and Mr. Septimus Sibley elected members of the Council.

There was, as usual, a large and interesting exhibition of specimens which have been added to the museum of the College during the past year; some are of special interest, and form valuable additions to this important collection.

THE SERVICES.

THE Indian Government has conferred a good service pension upon Surgeon-General B. Simpson, M.D.

ADMIRALTY.—The following appointments have been made:—Surgeon John Anderson M'Adam, to the *Penguin;* Surgeon Thomas Martyn Sibbald, to the *Duke of Wellington;* Surgeon Robert Forbes Bowie, to the *Superb;* and Surgeons Alfred John Pickthorne, James Henry Dawe, and East Apthorpe, to the *Duke of Wellington*, additional, for disposal.

ARTILLERY VOLUNTEERS.—1st Dorsetshire: Augustus Kinsey-Morgan, Gent., to be Surgeon.

RIFLE VOLUNTEERS.—4th Middlesex (West London): Surgeon G. E. Norton is granted the honorary rank of Surgeon-Major.—1st Cumberland: Surgeon M. W. Taylor is granted the honorary rank of Surgeon-Major.—1st Volunteer Battalion, the Norfolk Regiment: Acting Surgeon C. W. Doyle, M.B., resigns his appointment.

MEDICAL NOTES IN PARLIAMENT.

The Medical Acts Amendment Bill.

IN the House of Commons on the 23rd ult., on the consideration of the Lords' amendments to this Bill, Mr. Tanner remarked that when the Bill was under discussion in that House, a division was taken on the point whether the Universities of Aberdeen and St. Andrews should each have a member, or whether they should have one member between them. On that occasion the House came to the conclusion that it would be better to treat them collectively, and therefore he now moved that the House should disagree with the amendment which had come down from the Lords.—Mr. J. A. Campbell supported the Lords' amendment on the ground that it gave effect to the principle which this House had laid down in the first instance.—Sir L. Playfair, while sympathising very much with the hon. member for the county of Cork, hoped the House would agree with the Lords' amendment.—Mr. Sexton urged his hon. friend not to press his objection.—The motion was then withdrawn, and the Lords' amendments were agreed to.

Medical News.

UNIVERSITY OF DURHAM.—At the recent examinations for degrees in Medicine and Surgery the following satisfied the examiners:—

DOCTOR IN MEDICINE, FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Bately, John, L.R.C.P., M.R.C.S., L.S.A.
Cleghorn, George, M.R.C.S., L.S.A.
Crossman, Edward, L.R.C.P., M.R.C.S., L.S.A.
Eustace, Edward, L.R.C.P. Edin., L.R.C.S. Irel.
Fishbourne, Joseph Eustace, L.R.C.P. Edin., L.R.C.S. Irel.
Gowans, William, L.R.C.P., L.R.C.S. Edin.
McDermott, Joseph Patrick, L.R.C.S.I., L.K.Q.C.P.I.
Patrick, Robert, L.R.C.P. Edin., M.R.C.S.
Perkins, Whitfield, M.R.C.S., L.S.A.
Reston, Henry, L.R.C.P., M.R.C.S., L.S.A.
Tinley, Thomas, L.R.C.P. Edin., L.S.A.

DOCTOR IN MEDICINE (Essay).

Cook, Frederick W., M.B., M.R.C.S., L.S.A.
Edwards, W. Rice, M.B., M.R.C.S.
Parsons, J. Inglis, M.B., M.R.C.S.
Rodman, G. Hook, M.B., M.R.C.S., L.S.A.
Salvage, J. Valentine, M.B., L.R.C.P., M.R.C.S.
Tomson, Walter, Bolton, M.B.
Wigan, C. Arthur, M.B., M.R.C.S.
Wills, J. Pearce Bidgett, M.B., M.R.C.S.

MASTER IN SURGERY.

Baumgartner, H. Spelman, M.R.C.S., L.S.A., College of Medicine, Newcastle-upon-Tyne.
Caley, G. Neville, L.R.C.P., M.R.C.S., St. Mary's Hospital.
Platt, H. T., M.B., College of Medicine, Newcastle-upon-Tyne.

BACHELOR IN MEDICINE (Final Examination).

Arnold, Ernest C., M.R.C.S., St. George's Hospital.
Buss, Frederick, L.R.C.P., St. Bartholomew's Hospital.
Baumgartner, H. Spelman, M.R.C.S., L.S.A., College of Medicine, Newcastle-upon-Tyne.
Blacker, A. Barry, M.R.C.S., L.S.A., St. Thomas's Hospital.
*Caley, G. Neville, L.R.C.P., M.R.C.S., St. Mary's Hospital.
Carlyon, E. Trowbody, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital.
Coal, Arthur P. Gambell, M.R.C.S., St. George's Hospital.
Courteen, Raymond, M.R.C.S., St. Bartholomew's Hospital.
Cranstoun, C. Bruce, St. Thomas's Hospital.
Cross, Henry W., College of Medicine, Newcastle-upon-Tyne.
Davis, Hor, Middlesex Hospital.
Dimmock, Augustus F., M.R.C.S., L.S.A., King's College.
Dove, Augustus C., M.R.C.S., St. Bartholomew's Hospital.
Garrett, John Henry, University College.
Hamilton, Geo, Clarendon, L.S.A., London Hospital.
Hardwick, Arthur, L.S.A., Westminster Hospital.
Hickey, Evan Lewis, M.R.C.S., King's College.
*James, J. Thomas, F.R.C.S. Eng., Middlesex Hospital.
Jeffree, Frank, M.R.C.S., L.S.A., King's College.
Larking, Arthur Ernest, M.R.C.S., L.S.A., Guy's Hospital.
Low, C. W., L.R.C.P., M.R.C.S., L.S.A., St. Bartholomew's Hospital.
Manning, Philip Percy, King's College.
O'Connor, C. Patrick, University College.
Paige, H. B. Wood, College of Medicine, Newcastle-upon-Tyne.
Phillips, Edward, M.R.C.S., Queen's College, Birmingham.
Pace, William, College of Medicine, Newcastle-upon-Tyne.
*Rawes, William, M.R.C.S., London Hospital.
Richardson, W. G., College of Medicine, Newcastle-upon-Tyne.
Ruddock, W. James, College of Medicine, Newcastle-upon-Tyne.
Spoor, William Joseph, M.R.C.S., Middlesex Hospital.
Straughan, John, College of Medicine, Newcastle-upon-Tyne.
Sugden, Edward S. [illegible], St. Thomas's Hospital.
Sumpter, Bernors G., College of Medicine, Newcastle-upon-Tyne.
Turnbull, W., L.S.A., College of Medicine, Newcastle-upon-Tyne.
Wilding, James, L.R.C.P., M.R.C.S., Westminster Hospital.
*Young, E. Herbert, L.R.C.P., M.R.C.S., L.S.A. Univ. Coll.

* Second Class Honours.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At an examination recently held the following obtained the Fellowship:—

Archibald Adams, M.D., Indian Medical Department.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 24th ult.:—

Chick-Lucas, J. Robb Goodman, M.R.C.S., Bellevue, Brading, Isle of Wight.
Edsell, George Alfred, The Grove, Roulah-hill, Upper Norwood.
Hemming, Claude Philip, Highfield, Bishop's Waltham.
Luff, Arthur Pearson, Denmark Villas, Ealing.
Michelmore, George, M.R.C.S., Gloucester-street.
Pernewan, William, Redruth, Cornwall.
Seville, Charles Frederick, Mossley, Manchester.
White, Francis Silva, Lexham-gardens.

ON the 30th ult. their Royal Highnesses the Prince and Princess of Wales performed the ceremony of opening the new wing which has been added to the Royal Victoria Hospital for Children at Chelsea. The cost of the new building has been £7500, and the contributions already received amount to £4000.

ON the 25th ult. the new wing of the Queen Charlotte's Lying-in Hospital, Marylebone-road, was formally opened by the Princess of Wales.

AT a meeting of the City Corporation on the 1st inst. it was referred to a committee to consider the propriety of acquiring the Tottenham Marshes as an open space.

THE Metropolitan Board of Works on the 25th ult. decided to order from the Barrow Shipbuilding Company (Limited) a vessel capable of conveying 1000 tons of sewage sludge out to sea.

BEQUESTS.—Sir William Gillilan Johnson, late of Belfast, has bequeathed £250 to the Belfast Royal Hospital, £250 to the Belfast Ophthalmic Institution, and £100 to the Belfast Hospital for Skin Diseases.

SANITARY INSTITUTE OF GREAT BRITAIN.—The anniversary dinner of the institute will be held at the Holborn Restaurant on the 8th inst., and will be presided over by Captain Douglas Galton, C.B.

AT a meeting held on the 23rd ult. in the boardroom of the York County Hospital it was unanimously resolved that a Volunteer Medical Association for Yorkshire be formed.

HUDDERSFIELD INFIRMARY.—The Board of Management of this Infirmary have requested Messrs. H. Saxon Snell and Son to prepare designs for the enlargement of the building, and also a report as to the sanitary condition of the premises generally.

AN unfortunate teetotaller some months ago attended a temperance lecture, and was there informed that ammonia was the best substitute for alcohol. Having a pain in the chest, he took a tablespoonful of the drug, which caused his death after great agony. At the inquest the jury returned a verdict of accidental death.

PIROGOFF MEMORIAL CHURCH.—In the May number of the *Russkaya Starina* there is a picture of a handsome church of Byzantine architecture, with dome and cupola surmounted by a cross, which has just been erected over the grave of the illustrious Russian surgeon, Prof. Pirogoff, at Vishna, near Vinnitsa, in the province of Podolsk. Our medical contemporary, the *Track*, publishes a copy of this engraving in its issue, No. 20.

NORTH LONDON HOSPITAL FOR CONSUMPTION.—The festival dinner in aid of the funds of this institution was held on the 23rd ult., when subscriptions and donations amounting to £1256 were announced. The hospital, which is unendowed, and depends entirely upon voluntary contributions, receives patients from all parts of the kingdom, and 160,000 patients had been relieved since its foundation. The total receipts from all sources during the year 1885 were £1837 11*s.* 2*d.*, against £3029 2*s.* 6*d.* in 1884, and £2736 3*s.* 1*d.* in 1883.

NATIONAL DENTAL HOSPITAL.—On the 29th ult. a dinner in aid of the funds of this institution was held, the chair being taken by Alderman Sir Robert N. Fowler. In proposing prosperity to the National Dental Hospital, the chairman stated that the hospital had been founded in 1861, and after existing a quarter of a century came forward for the first time to appeal for support—after the fashion followed by so many other charities—at a dinner. Since its institution it has relieved 221,422 cases, the number of patients in 1885 being 20,367, and of cases of operation 37,364.

LADY DUFFERIN'S FUND.—The managers of this fund have published an account of the progress made in supplying female medical aid to the women of India, in which they state that the attendance at the dispensary in Calcutta is increasing rapidly, and that the institution promises to be a great success. The North-Western branch association is establishing a female hospital at Allahabad, while the female medical school at Agra shows great vitality. A provincial branch association has been formed at Rangoon, and from Lahore, Delhi, and some of the native States come applications for more lady doctors. The conditions on which the Queen's and Viceroy's medals are to be awarded will shortly be made public. Money is, however, urgently required, the sums already subscribed having proved quite insufficient to meet the requirements.

THE Lord Chancellor has added to the Commission of Peace for Cardiff the name of Mr. D. E. Jones, L.R.C.P. Ed., F.R.C.S. Ed.

ANCIENT ALCHEMIST'S LABORATORY.—In connexion with the British Association meeting which is to be held in Birmingham, there is to be an Exhibition, and Messrs. Southall Bros. and Barclay are desirous of representing an ancient alchemist's laboratory. They have received most generous help from Professor Redwood, Henry Irving, Esq., Lawson Tait, Esq., Messrs. Corbyn and Co., Messrs. Godfrey and Cooke, and others, and they will be greatly obliged to gentlemen who possess old utensils, implements, fixtures, &c., if they will forward particulars in case they are disposed to lend them for the occasion. The Exhibition will remain open for about six weeks, commencing the latter part of August.

TANFANI v. WINSLOW.—This case was decided in the Court of Queen's Bench on the 25th ult. The following are the facts:—Madame Tanfani, suing as a married woman under her separate estate, brought an action against Dr. Winslow for alleged false imprisonment in Sussex House Asylum. The lady was confined as long ago as 1878, but being then a *femme couvert* she could not bring her action until after the passing of the Women's Property Act in 1883, when she became a *femme sole*. Dr. Winslow received the lady on the order signed by the sister and by two medical men, against whom actions are still pending. Within three days of her incarceration in an asylum, she was visited by the Commissioners in Lunacy, and again after she had been there a few weeks, who pronounced on her insanity. She had also been confined in Rome, and was brought over from Italy by two men. Dr. Winslow appeared in person to defend this action. Without requiring Dr. Winslow to call witnesses or address the Court, Mr. Justice Manisty submitted to the jury that what Dr. Winslow did was perfectly justified, and the jury returned a verdict for the defendant.

ST. THOMAS'S HOSPITAL.—On Wednesday the Dean of Westminster distributed the prizes at this hospital for the summer session 1885-86. The Dean offered some good counsel to the younger members of his audience, which he enforced and illustrated by a telling anecdote. Among the successful students were Mr. J. W. Wheaton, who took the College Prize of £15 and the Mead medal for practical surgery, and who attained the second place in an open competition for the Murchison Scholarship, and Mr. J. Macevoy, who took the College Prize of £10, a bronze medal for practical medicine, and was bracketed equal with Mr. Wheaton in the competition for the Murchison Scholarship; Mr. A. F. Stabb obtained an Entrance Science Scholarship of £100, the William Tite Scholarship of £30, and special mention for practical medicine; Mr. E. Solly took the Solly Medal and a prize of £25; Mr. H. J. Smyth gained the Treasurer's Gold Medal for general proficiency and good conduct; Mr. F. C. Abbott carried off a College Prize of £15, the Peacock Scholarship of 40 guineas, and a certificate of honour; and Mr. C. H. Eccles, a College Prize of £15 and another of £20.

QUEEN'S COLLEGE, BELFAST.—At the General Examinations at the close of the Session 1885-6 the following were awarded prizes:—Practical Chemistry: Robert Thomson and Alexander Jamison. Zoology: Senior Division—James Taylor and J. S. Morrow; Junior Division—E. W. McBride, Douglas Maconachie, John Jamison and H. J. Heron (equal), and Alexander Jamison. Anatomy and Physiology: Third Year—J. L. Livingstone; Second Year—John Campbell; First Year—James Taylor, H. J. Heron and James McConnell (equal), John Larkin and Robert Wilson (equal). Practical Anatomy: Third Year—John Campbell, D. C. Smiley, R. C. McCullagh, J. L. Livingstone, R. W. Haslett, F. E. Murray, G. A. Waring (honourable mention for Dissecting); Second Year—J. M. Hall, Robert Wilson, W. P. M. Eldowney, and S. J. Parker; First Year—James Fulton, S. H. Withers, John Larkin, and D. H. Hamilton. Medicine: Second Year—W. B. McQuilty, S. R. Collier, and G. S. Thomson; First Year—John Campbell and J. M. J. Downer. Surgery: G. H. Thompson and R. J. Duffin (equal), John Campbell and Simon Ryan. Materia Medica: M. H. Quarry, Andrew Burgess, William Ekin, and J. S. Downer. Midwifery: W. Elliot, J. Campbell, and W. Kilbeen (equal), W. Hamilton and R. Esler (equal), James Hunter and H. L. Mac Kisack (equal, with hon. mention).

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

AIRD, CHARLES, M.B.Aber., has been appointed Assistant Medical Officer to the East Riding Asylum, Beverley, vice Broatch, M.B.Ed.

AUDLAND, W. E., L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon to the General Infirmary, Northampton, vice J. Oswald Lane, M.D.Cantab., resigned.

CAMPBELL, HARRY, M.D., B.S.Lond., M.R.C.P., has been appointed Assistant Physician to the North-West London Hospital.

ELLIS, WILLIAM HENRY, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health to the Shipley Urban Sanitary Authority.

FITZPATRICK, J. V., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Moville Dispensary District, Public Vaccinator, Sanitary Medical Officer, and Medical Officer to the R. I. Constabulary, vice Sproulle, deceased.

FROST, W. ADAMS, F.R.C.S.Eng., L.R.C.P.Lond., has been appointed Ophthalmic Surgeon to the Victoria Hospital for Children, Chelsea.

HILL, F. A., M.D., M.R.C.S., has been appointed Medical Officer for the Kilburn District of the Parish of St. John, Hampstead.

JOHNSTON, FRANCIS, M.B., C.M.Glas., has been appointed Senior House-Surgeon to the Liverpool Infirmary for Children, vice A. Stookes, M.B., C.M.Edin., resigned.

MITCHELL, ADAM G., L.R.C.S., L.R.C.P.Ed., of the Peninsular and Oriental Steam Navigation Company's Service, has been appointed to the *Salley*.

MURRAY, ANDREW, M.D., B.Ch., has been appointed Medical Officer for the Hampstead District of the Parish of St. John, Hampstead.

PENNY, WILLIAM J., F.R.C.S.Eng., has been appointed Assistant Surgeon to the Bristol General Hospital.

PENROSE, FRANCIS GEORGE, M.D.Lond., M.R.C.S., has been appointed Medical Registrar to the Hospital for Sick Children, Great Ormond-street.

RANKIN, MALCOLM A., M.D.Glas., has been appointed Medical Officer to the Workhouse of the Luton Union.

RIGDEN, ALAN, L.R.C.P.Lond., M.R.C.S., has been appointed Junior Assistant Medical Officer to the Salop and Montgomery Counties Asylum, Shrewsbury, vice P. M. Earle, L.R.C.P., L.R.C.S.Ed., resigned.

SUCKLING, C. W., M.D.Lond., M.R.C.P., has been appointed Consulting-Physician to the Birmingham Orthopædic and Spinal Hospital.

WITHERS, J. SHELDON, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Ashton-on-Mersey District of the Altrincham Union.

Births, Marriages, and Deaths.

BIRTHS.

EMMETT.—On the 26th ult., at Woolville, Portsmouth, the wife of Richard Emmett, M.R.C.S., L.R.C.P.Lond., of a son.

FISHER.—On the 25th ult., at West Walk, Dorchester, the wife of Fred. Bazley Fisher, M.R.C.S., F.R.C.P., of twin daughters.

GARLICK.—On the 22nd ult., at 32, Great James-street, London, W.C., the wife of George Garlick, M.D.Lond., of a son.

GRAHAM.—On the 24th ult., at 17, Queen-street, Wigan, the wife of Charles R. Graham, M.R.C.S., &c., of a son.

THOMPSON.—On the 27th ult., at Suffolk-place, Sevenoaks, the wife of Herbert Thompson, M.R.C.S., of a son.

WEBSTER.—On the 27th ult., at St. Alban's, the wife of F. R. Webster, M.R.C.S., of a son.

WEBSTER.—On the 8th ult., at Golcar, Yorkshire, the wife of A. G. Webster, M.R.C.S., of a daughter.

MARRIAGES.

COOK—CORNWALL.—On the 24th ult., at St. James's Episcopal Church, Aberdeen, James Will Cook, M.B., C.M., of Bury, Lancashire, to Jane MacKay, second daughter of J. R. Cornwall, Esq., of Queen's-road, Aberdeen.

HAYES—MUIR.—On the 24th ult., at the Bowdon Congregational Church, by the Rev. Alexander Mackennal, B.A., and the Rev. Joseph Corbett, D.D., of Glasgow, James Hayes, M.R.C.S., L.R.C.P.Lond., eldest son of John Hayes, J.P., of The Limes, Leigh, to Jessie Geddes, elder daughter of Alexander Muir, of Altrincham.

STEEL—OWEN.—On the 23rd ult., at the Parish Church, Llandilo Pertholey, near Abergavenny, by the Rev. James Owen, uncle of the bride, assisted by the Rev. Allen Steel, uncle of the bridegroom, William Dyne Steel, M.D., of Abergavenny, eldest son of S. H. Steel, Esq., M.B., of Abergavenny, to Mary Emily (Trottie), eldest daughter of His Honour Judge Owen, of Ty Gwyn, near Abergavenny.

STURGE—SHERRIFF.—On the 1st inst., at St. Andrew's Church, Westminster, by the Rev. Melvill Haslope, Wm. Allen Sturge, M.D., of Nice, France, to Julia, daughter of the late A. C. Sherriff, M.P. for Worcester.

DEATHS.

BARRINGER.—On the 23rd ult., at Parkhurst-road, Thomas Stevens Barringer, M.D., in the 75th year of his age.

BATT.—On the 6th ult., at Gloucester, R. B. D. Batt, M.R.C.S., L.S.A., aged 25.

COLE.—On the 27th ult., at Ely, George Cole, Surgeon, aged 79.

OGILVIE-FORBES.—On the 25th ult., at Boyndlie House, by Fraserburgh, Aberdeenshire, George Ogilvie-Forbes, M.D., of Boyndlie, formerly Professor of Institutes of Medicine in the University of Aberdeen, aged 65.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Letters requiring notice must be authenticated by the name and address of the writer.

We cannot undertake to return MSS. not used.

UNQUALIFIED PRACTICE AND THE NEW MEDICAL ACT.

General Practitioner says: "I have seen some glaring blunders smoothed over by signature of principal, even craniotomy, by an unqualified man, single-handed, and death certificate by principal for both mother and child," and asks, Does the Medical Act affect such cases, or the legal prosecution of the offenders? We are sorry to say the Medical Act leaves this grave question just where it found it, and does nothing to deter offenders. We must trust to coroners and medical men who are called in to such cases for the exposure of a great evil.

Enquirens (Porthleven) is referred to a general notice at the head of this column.

Mr. David Norman (Glasgow).—In about three weeks or a month.

THE POSTAL MICROSCOPICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—Thinking there may be many members of the profession who do not know of the existence of a special Medical Section for the circulation of histological and pathological slides in the above Society, I ask you to insert this letter, in the hope that it may come under the notice of gentlemen interested in pathology, &c., and to ask them to assist the section by becoming members or obtaining friends to do so. The great advantages of the Society are (1) that it takes up very little of their time (only that in which the specimens and notes are examined, and once a year a new selection to be got ready and sent to the secretary to forward on the various circuits), and (2) that members who cannot attend the meetings of societies for various reasons, and those who live too far distant from them, are thus brought into communication, ideas and notes are exchanged, and much useful information is brought to light, the specimens often presenting features of special interest. The section is gradually increasing, and we hope before long to have many more among our ranks. Those gentlemen who were students when pathology and histology were only in their early growth would in this way become acquainted with the progress of the sciences and the various processes used in them. Of course, the slides of the Medical Section are not circulated amongst any but those of their own professional section. Should any further particulars be desired, they can be obtained from the secretary, Mr. Alfred Allen, 1, Cambridge-place, Bath.

I am, Sir, yours truly,

Manchester, June 28th, 1886. V. A. LATHAM.

MEDIÆVAL INNS.

THE pestilences of antiquity and of the Middle Ages were simply the explosions of disease engendered by long periods of insanitary living. Want of cleanliness was prominent among the predisposing causes. In Gustav Peyer's "Geschichte des Reisens in der Schweiz" ("History of Travel in Switzerland") a graphic account is given of the mode in which the wayfarer was housed and entertained in the hostels of the sixteenth century, which may be read as a supplement to the still more graphic description of the same in Sir Walter Scott's "Anne of Geierstein," in the century preceding. In the year 1520 Erasmus wrote to a friend:—"On arriving at your inn, there is no one to receive you, so that there might be no appearance of lying in wait for guests. After you have shouted a long time, a head is thrust out of the little window of the stuffy apartment. You ask for stabling, and the reply is a wave of the hand to the outhouse in question. There you may groom your horse to suit yourself, for no ostler is within reach. Your horse provided for, you make your way, accoutred as you are—boots, baggage, and dirt—to the apartment aforesaid. The room is common to every guest, and there you draw off your boots, replace them by shoes, and even change your linen. On one side of you an 'arrival' is combing his hair; on the other a second is mopping the sweat off his person; while a third is polishing his shoes or riding-boots. You arrive at 4 P.M., but yet you may not dine till 9, or not until 10 P.M.; for the meal is not served till all that the inn can hold have come. As soon as each one has taken his place at table, there enters the sour-visaged Ganymede—grey-bearded, close-clipped as to his head, repulsive of aspect and foul as to his apparel. Then come with great pomp the dishes. Finally the bearded attendant makes his rounds, in his hand the dinner slate, on which he has described with chalk sundry hooks and eyes. Those who can read the hieroglyphics lay down their money on the slate, one after another, till it is covered, and so he marks off those who have paid. No one disputes an unjust reckoning. If, weary from your journey, you wish after supper to go to bed, you are told you must wait till all the other guests are ready to lie down. Then everyone is shown his 'rabbit-hutch'—a bed, and nothing more; for, besides the bed, there is no furnishing to it which you can use. The sheets most likely have not been washed for six months." So, freely translated from his idiomatic Latin, wrote the dainty humanist, whose efforts in behalf of the Reformation were *motives* by other abuses than those of ecclesiastical authority. In explanation of the remark "that there might be no appearance of lying in wait for guests," Herr Peyer quotes a decree of the Zurich Town Council of 1402, to the effect that "fremdenfängerei"—that is, touting for strangers—was forbidden under severe penalties. Certainly, the landlords of the day did their best to make the enactment superfluous.

Mr. R. T. Thomas.—The possession of the L.R.C.P. Lond. does not entitle its holder to style himself "Doctor" on his door-plate.

APPLICATION OF FORCEPS.

To the Editor of THE LANCET.

SIR,—I fully concur with Dr. Brand of Driffield as to the comparative facility of the application of forceps by introducing the upper blade first; and I have often been puzzled to discover the reason why the text-books, almost, I think, without an exception, recommend the lower blade to be introduced first. Ever since I began practice, nearly fifty years ago, I have used, except in very few cases, the double curved forceps, introducing the upper blade first by the hollow of the sacrum, and gliding it by gentle rotation into position. I then introduce the lower blade, also by the hollow of the sacrum, and glide it into position, when, by gentle manipulation of the handles, the instrument is easily locked. When the operation is performed in this manner, there is no occasion to disturb and alarm the patient by bringing her to the edge of the bed, nor is the aid of an assistant required.

I am, Sir, yours faithfully,

Tring, June 28th, 1886. EDWARD POPE, M.R.C.S.

STRANGE CAUSE OF MUMMIFICATION.

M. BROUARDEL has reported to the Paris Academy of Medicine upon the mummification of the body of a young woman which was found in a heap of straw in a cellar. The cellar had not been opened for eight months. The body was in a remarkable state of preservation. The mummification was due, according to MM. Brouardel and Mégnin, to myriads of acari of various kinds whose eggs were embedded in the tissues.

C. M. M.—The words *wood sorrel* in our last issue should have been in inverted commas, as they were copied from a report of the case in a contemporary. "Wood sorrel" is undoubtedly the popular name for *Oxalis acetosella*. We believe the plant ingested was the sorrel dock (*Rumex acetosa*); possibly it was the sheep sorrel (*Rumex acetosella*).

Dr. Russell (Glasgow).—Bell and Sons, York-street, Covent-garden, London, W.C.

A QUESTION IN MEDICAL ETHICS.

AN ex-medical officer of health, of great practical experience in house sanitation and in tracing diseases to sanitary defects, asks if it would be unprofessional to advertise his services for sanitary house inspection, either openly or under a *nom-de-plume*. Hitherto, so far as we know, such a practice has not been resorted to, except in so far as the names of medical advisers to the different sanitary associations are appended to the advertisements of those societies. If such advertising as is indicated in the question put to us were limited to the professional journals, as is the case in respect of the care of the insane, &c., we could hardly raise objection to it; but beyond this the practice is one which we could not advocate.

J. F. (Barrow-in-Furness).—The tragic end of the King of Bavaria has given a fresh start to observations on the "law of hereditariness." Dr. P. Maréchal, in an interesting paper, reminds us that the Royal House of Spain exemplifies a transmitted neuropathy lasting 250 years. John II. was imbecile; Isabella of Portugal mad; Ferdinand the Catholic melancholic; John, surnamed "the Mad," a victim of hallucinations; Mary Tudor hysterical; Charles V. epileptic and superstitious; Philip II., his son, a homicidal mystic; Philip III. first imbecile and then mad; Philip IV. imbecile; and his two sons, Prosper subject to convulsive fits and Charles VI. imbecile, melancholic, and finally mad. With this last, who died without issue in 1700, the family became extinct.

Subscriber.—We should recommend the interior regions of South Africa, Australia or New Zealand. The towns should be avoided.

OVERCROWDING IN THE PROFESSION.

To the Editor of THE LANCET.

SIR,—I read with some interest a letter in your last issue, signed "L.C.P.S. Que.," pointing out that the profession is "full" in Canada. Will any of your correspondents tell me if they know of any spot in this world where that is not the case? This leads me to ask another question, What may we expect the condition of the profession to be in, say, half a century, if some steps are not taken by those in authority to check in some way the overcrowding which is making itself painfully felt more and more year by year? Month after month we see pass-lists appearing, swelling the tide of practitioners, and making each one's share of bread-and-butter less and more precarious. The inevitable endency of this must necessarily be to lower the status of the profession in the eyes of the public. I know of very few small towns or country places where there are two or more medical practitioners without a perpetual ill-feeling in the said practitioners towards each other, in many cases almost amounting to strife. And why is this? It is because these members of an honourable profession entertain jealous feelings towards one another, the one always apparently thinking that the other intends to let no opportunity pass of robbing his neighbour of his patients. And is this fear wholly without foundation? I grieve to say it is not. A personal friend of mine, a M.D., had recently the pleasing experience of losing a club because a brother practitioner, a M.R.C.S. and L.S.A., kindly undertook the job at a shilling a head less. Then, again, another sign of the overcrowding may be found in the ridiculous salaries which "assistants" may expect to get. I have myself been offered £1 a week for my services, which I was fortunately in a position to decline with thanks; but I have no doubt that there are many working both day and night, with hardly a moment to call their own, at such a fee, and albeit are expected to—and must, indeed—keep up a good appearance on such a pittance. A remedy is not far to seek, if only those who are in authority will exercise their power. Why is it that men (and I have known not a few who have done this), after repeatedly failing at one of our universities, can without trouble obtain a qualification in medicine and surgery at the Colleges?

In conclusion, I would like to ask your correspondent if a graduate in medicine and surgery of a British university cannot practise in Canada without passing an examination in Ontario or Quebec, as he would seem to imply.

I am, Sir, yours faithfully,

Yorkshire, June 28th, 1886. "FELIX HOLT."

CIRCULAR CLINICAL THERMOMETERS.

IN reference to a letter from "M.D. Durh.," in our issue of June 19th, a correspondent writes to ask for further opinions in confirmation or otherwise of the unfavourable testimony therein borne to the value of circular clinical thermometers.

Mr. Tom Lee.—The question surely scarcely requires an answer. The names were fictitious.

DR. ALLEN'S CASE OF EXTRA-UTERINE PREGNANCY.

To the Editor of THE LANCET.

SIR,—Will you allow me to say that the most important lessons of this case are the illustrations it affords of the futility of tapping as a method of diagnosis or treatment and its great dangers. In this case an exploratory incision would have secured at once a correct diagnosis, and would have opened the way to successful treatment.

I am, Sir, yours truly,

Birmingham, June 26th, 1886. LAWSON TAIT.

THE ARCHÆOLOGY OF SURGERY.

J. H. (Carlisle).—Sir James Young Simpson's very clever work on "Acupressure" (Black, Edinburgh, 1864), which, though its *raison d'être* was almost immediately annulled by Listerism, may still be read with profit as a contribution to the history of medicine. It was not till 1564 that surgery, at the instance of Ambroise Paré, revived the deligation of bleeding vessels with simple threads described by Celsus, and substituted it for their cauterisation with red-hot irons. Attempts to find an earlier origin for the ligature have not been successful. In the excellent "Handbook to the National Museum in Naples," its English editor, Mr. E. Neville Rolfe, thus describes the beautiful fresco of Æneas Wounded: "The painting, which is quite unimpaired, represents an episode of the Trojan War. Æneas leaning on his spear, with an expression denoting pain, has his arm round the neck of Julus, who weeps. A surgeon is on his knees, *picking up the artery with forceps*. Other warriors look on, while Venus appears from Olympus with a sprig of balsam." The proper reference is to the Latian War, as told by Virgil, who gives the story of Æneas's hurt in the twelfth book of the Æneid, verse 383 *et seqq*. It was no artery that the surgeon tried in vain to take up in the hero's wound; it was the arrow-head embedded in the tissues that had to be extracted, by one of the methods described by Celsus (Book vii., c. 5, "De Telis e Corpore Extrahendis"). The surgeon failed, as Celsus could have told him he would, and Venus had to interpose with an infusion of Cretan dittany, which, used as a fomentation, caused the arrow-head to drop from the wound without farther ado. So sound a scholar as Mr. Rolfe would do well before adopting the views of his Italian confrère to test them by classical authority.

Mr. W. H. Bourke.—No doubt the secretary of the Brussels Medical Graduates' Association, Dr. Pocock, The Limes, St. Mark's-road, North Kensington, will, on application, answer the questions of our correspondent.

Dr. J. Lowe (London).—Yes, if not long.

SEA AIR IN SCROFULA.

To the Editor of THE LANCET.

SIR,—Mr. Frederick Treves, in his able and instructive paper upon the treatment of scrofulous neck (*vide* THE LANCET, June 5th), says:—"In the choice of a sea-side resort, I think it matters little whether the spot be east, west, north, or south, so long as it presents this feature—a beach upon which a large extent of seaweed lies exposed at low water. Iodine is, or can be, obtained from seaweed; and it is reasonable to conjecture that this volatile substance may be given off into the atmosphere when acres of seaweed are drying in the summer sun. An iodine-laden air is an ideal atmosphère for a scrofulous person. Certain it is that those sea towns are most beneficial where this condition is pronounced; and it is to this circumstance, and the fact that it lies surrounded on three sides by the sea, that Margate probably owes its great repute as a place of healing." This question of free iodine in the air under the conditions named is a very interesting one. Upon consulting an eminent professor of chemistry, and recent works upon the subject, I find that it is not universally admitted that atmospheric air ever contains free iodine; if present, the quantity is so small as to render detection almost impossible. Seaweed contains iodides which can be dissolved out of the fresh weed by fresh water; a fall of rain would supply this water. Ozone sets free iodine from iodides, and ozone being always present in good air we might suppose that it would do this. Where, however, large quantities of seaweed are exposed at low water other processes are at work—viz., those of decay and oxidation—which give rise to products the smell of which is probably often mistaken for that of iodine or ozone. These processes use up the ozone, and convert the free iodine, if there is any, at once into an iodide. It has therefore yet to be proved by direct experiment that the air of such places contains free iodine, notwithstanding that Mr. Treves speaks of "an iodine-laden air." The fact that Margate is so freely exposed to the sea air is most probably the cause of the benefit that scrofulous patients receive whilst there. This fact Mr. Treves mentions; and he would probably be disposed to admit that a sea voyage, under favourable conditions, would be even more likely to benefit such patients. This, however, he could not attribute to the seaweed that is in the water, any more than he could the saltness to the salt fish contained therein.

I am, Sir, yours faithfully,

Southport, June 15th, 1886. EDWARD DAY MCNICOLL.

ERRATUM.—In our report last week of the meeting at Lambeth Palace, page 1251, the name of the organiser should have been printed Mr. R. Garrard Kestin, not "Keskin."

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from:—Dr. Quinlan, Dublin; Mr. W. Whitehead, Manchester; Dr. Harkin, Belfast; Mr. L. Tait, Birmingham; Dr. E. B. Medical Diary for the ensuing Week.

Monday, July 5.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

Tuesday, July 6.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, July 7.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Daly, Mr. Doran, and others. Dr. Herman: Case of Chronic Abscess of the Urethra.—Dr. Champneys: Observations on the Uterine Bruit.—Mr. Doran: Papilloma of the Fallopian Tube.

Thursday, July 8.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, July 9.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, July 10.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
TO CHINA AND INDIA		One Year	1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES		Ditto	1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

"THE LANCET"

THIRD SPECIAL SUPPLEMENT,

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND.

HOSPITAL SUNDAY RESULTS, AND AFTER.

HOSPITAL SUNDAY and the Hospitals Week for 1886 are past and gone. Those who have worked in the cause of the hospitals have ample reason to thank GOD and take courage. The effect of the public meetings in all parts of London, attended as they have been in increasing numbers, and culminating in the enthusiastic gathering at Stratford on Saturday afternoon, have borne good fruit. Thanks to the press, and especially to *The Times*, *Daily Chronicle*, *Morning Post*, *Daily Telegraph*, *Echo*, and *Globe*, amongst our daily metropolitan contemporaries, the proceedings have attracted and fixed the attention of all classes, notwithstanding the political excitement and the approaching elections.

From very varied sources evidence is forthcoming that the clergy and ministers of religion have been encouraged to renewed exertion on behalf of all the hospitals. Some have written to express their indebtedness for the help they have received from THE LANCET Special Supplements. Many others, more than on any former occasion, have studied the hospital question, and have given the results to their congregations in special, touching, and eloquent sermons. All have doubtless done their best. This is as it should be; and evidence of improved returns from places of worship in every district is already forthcoming. Indeed, there is reason to hope the total sum collected this year will be the largest yet received on Hospital Sunday.

We heartily thank preachers, speakers, and workers for what they have done; and we feel confident that if opportunity is taken to improve the machinery and organisation during the winter months, the amounts raised on Hospital Sunday will show a continuous increase year by year. Not only have the speakers and preachers roused the people, but they themselves gratefully acknowledge that this question has made a distinct advance in their own minds, and that the meetings, discussions, and publications have been helpful to an unforeseen extent.

THE REV. CANON FARRAR, D.D.,

ON

THE CHRIST-LIKE WORK OF THE HOSPITALS.

THE following are the chief points of an eloquent sermon preached by Canon Farrar at Westminster Abbey from the text,

"Who went about doing good."—Acts x. 38.

DIFFICULTIES OF DISBELIEF.

To anyone who will open his heart to the revelation of God, who will listen with quick-eared spirit for the whispers of His voice, it will become more and more impossible to disbelieve in Christ. Nothing, indeed, is easier than to make oneself a sceptic. A man has but to give himself wholly to the world; he has but to drown himself in an avaricious, an impure, a selfish life; he has but to neglect prayer and public worship, and the care of his moral being, and then, star by star, every gleam of moral conviction and spiritual truth will die out of his soul. In the black pools of subterranean caverns it is found that the fish are eyeless. They have lost a capacity which they could not exercise. Even so men who love darkness lose the apprehension of light. Men who will not see God soon find that they cannot.

THE BEST EVIDENCE OF CHRIST'S DIVINITY.

It has been said that the best evidences for the divinity of Christ are Christianity and Christendom. But there is a better still. It is Christ Himself. There is in these days much argument about Christ. But the one argument for our adoration of Him who transcends all others, the one which has forced even from sceptics a burst of acknowledgment, is His character, His guilelessness, His unique, supreme, transcendant superiority. For nearly nineteen centuries has the fiercest light of criticism and history beaten upon the records of the life of Christ, yet He still stands alone and unapproachable at the summit of all grandeur and holiness. The masses of mankind have failed—even God's purest saints have failed—not merely to attain to the consummate splendour of His spiritual perfectness, but even to grasp the meaning of more than some one fraction of His example. All these centuries of Christian history are but a comment on the divineness of His perfections, and therefore an ever-accumulating confirmation of the truth that He was not only the Son of Man but also the Son of God.

THOMAS A KEMPIS.

For during all those centuries the world was indeed learning from Him all that was best and most beautiful in its thoughts and in its conduct. Yet, all the while, even the Christian world was losing indefinitely from incapacity to grasp any more than one part of His example. So far as it followed Him, it was blest; so far as it did not comprehend Him, it was unblest. Take, by way of illustration, the exquisite religious manual of the Middle Ages—the Imitation of Christ, usually attributed to Thomas à Kempis. It has been more popular than any religious book ever written since the days of the Apostles; more popular even than our own "Pilgrim's Progress." Sceptics have valued it as well as saints. The "brief quivering sentences," its simple scriptural imagery, its charm of holy quietude, have come home with a sense of blessing and elevation to thousands of souls. In reading it we seem to be resting in some scene painted by Perugino or by the youthful hand of Raphael, where we see nothing but what is lovely and pure and sacred, and where there are none but sweet and holy faces gazing ever on the mother and the child.

BEING ALONE WITH THE ALONE.

Now, doubtless, for any noble life there must be something at least of this interiorness, of this detachment from the world, of this being alone with the alone. But it must only represent one side of life. If we must imitate Christ in His love for occasional solitude, His communings with His Heavenly Father under the starlight, in desert places, on lonely hills, we must imitate Him also in His immense beneficence. The life of meditation must issue in the life of action. We are not meant to be hermits in the wilderness, or to fence ourselves off in the cloistral cell from the coarse, intrusive elements of man. The world we are meant to live in is not in the least like the soft scenes of Perugino, bathed in pellucid air; nor are the streets we tread peopled with the sweet, serious faces of Fra Angelico. There are no meadows of asphodel on this side the grave, nor did Christ come to found some spiritual aristocracy on the Galilean hills. The retirement of Paul in Arabia must be supplemented by his daily battle, his league-long wanderings, by his toil in Corinth, his martyrdom at Rome; the seclusion of John in Patmos, where from the glowing rocks he could see nothing but the white wings of seabirds breaking the sunlit azure of the sea, must be but an episode to the work of John in the busy streets and wrangling marts of Ephesus, and among the prodigals and harlots there. Yes, the "Imitatio Christi" is an exquisite book, yet it reflects but one ray of the sevenfold light. It wholly passes by that element which St. Peter gives as the summary of our Lord's activity that, "He went about doing good." The Christianity of the "Imitatio" is purely individual. It is not the Christianity which overcame, which civilised the world. It had but one precept, Fly from this wicked world. Whereas the Gospel, the Gospel of the living Christ, says, Fight for this wicked world; make it purer, make it happier, make it better. Live for it in active kindness, as Christ lived for it; die for it (if need be, amid its anger and ingratitude) as Christ died for it. Save it, indeed, you cannot as Christ saved it by the one sacrifice of Himself once offered; help to save it by teaching of His redeeming truth, by the following of His daily example, by the continuance of His holy work.

"HE WENT ABOUT DOING GOOD."

And this was His example: "He went about doing good." For thirty years, indeed, He lived as the carpenter of Nazareth; lived as we have all to live, surrounded by common human influences, engaged in common daily duties, earning bread by toil of brain or sweat of brow, with mother, brethren, and sisters in His village home. This He did to show us that there is nothing unsacred, nothing ignoble, in our common daily duties, the anxieties, the domesticity, the ordinary surroundings. Not otherwise could He have revealed to us the dignity of man simply as man; the sacredness of home, be it never so homely; the possibility, by pureness, by kindness, of living even in the lowliest hovel as a son of God. But when His life burst into the consummate glory of His ministry, then "He went about doing good." Where do you find Him? You will not find Him in some deep seclusion meditating over an open grave; or sitting, with a skull before Him, beating His breast with a stone in a hermit's cavern; or elaborating minutiæ of legalism in some school of the rabbis; or absorbed in ritualism among bands of sacrificing priests. No; but you will find Him everywhere in the bright, busy, varied, suffering, common life of a man with men; attending their feasts and marriages, smiling with their laughter, weeping amid their tears, teaching in their synagogues, healing the sick, cleansing the leper, releasing the tortured soul of the demoniac, restoring to father and mother and sister their much-loved dead. You will find Him taking the little children up in His arms and laying His hands upon them and blessing them. You will find Him giving sight to the blind, and hearing to the deaf, and consolation to the sorrowful, and self-respect to the despised, and love to the hated, and to the most fallen the conviction that there might yet be joy in Heaven for them. You will find Him doing the work of the Good Physician for men's bodies as well as for their souls. And if there be one scene which strikes the three first evangelists alike as one which most sets forth His glory, it was that evening when, while the rosy sunset fell on the silver lake, the stillness of the sabbath twilight was broken as the people thronged to Him with their demoniacs and their diseased. The groans and sighs of that collective misery touched his inmost soul. He suffered with those whom He saw suffer; He sighed for them; His heart bled for them; He bore their griefs; He carried their sorrows; and as He moved amongst them in His love and tenderness, His heart was thrilled with a more than human rapture, as He laid on each unhappy and tortured sufferer the touch of His healing hand.

THE SECRET OF THE LIFE OF CHRIST.

Yes! Sympathy, not seclusion; beneficence, not asceticism; mercy, not sacrifice; love, not Pharisaism. There, for those who care to learn it, is the secret of the life of Christ. He went about doing good. And what is the lesson for us? What is it which Christ's voice says to us across the centuries? It says to us, You are living in a world of sin and sorrow. The sorrow touches you all that you may learn a common sympathy. You may shut out for a time—yea, for years,—in slothful luxury and in selfish isolation, the still, sad music of humanity, the moan of its anguish, the cry of its oppression. You may live for yourself, not for others, not for God. The worse for you. You cannot escape from the solidarity which makes you one of a fallen and ruined race. You cannot shut yourself up in some sweet circle of the orthodox, or of the elect, and give to your selfish spleen the name of religion. Old age will steal upon you. Pain will lay upon you her fiery finger. The pale, chilly, shadow of death will glide into your houses. And thereby the Lord bids you leave your callous-hearted worldliness, or your cliques of selfish religionism, and take your part, as He did, in the suffering, struggling world. He came to enlighten its errors, to break the yoke of its oppressors, to lull its pangs with an everlasting anodyne, to give to its living and its dying an immortal hope. He came to send into the ravage and the misery ten thousand white-winged messengers of mercy, to minister at least to the anguish they cannot extinguish, and to move, like angels, in the midst of it, with hearts of compassion, and words of healing love.

WORK FOR YOUR FELLOW MEN!

And this voice says further to us, You, each in your measure, must thus work for your fellow-men. Misery and anguish and disease, the outcome of sin and guilt, the fatal legacy of the Fall, are not to be ignored, nor shunned, nor acquiesced in as inevitable necessities. We have two duties towards them—the one is to alleviate, the other to prevent. The latter is the nobler work and the most neglected. Nine-tenths of the disease and misery of man is preventable. It is physically preventable; it is morally preventable. Physically, for much of it rises from the infraction of natural laws; morally, for that which has its outlet by human suffering has, to a very great extent, its inlet by human crime. Divert the runnel and you escape the flood; prevent the sins and you obviate the catastrophies. Go to any of our great hospitals. Look at that poor little Lazarus suffering from a complication of leprosies to which he was born. What made him so? The will of God? No! but the vice of his parents. Look at that poor bruised woman felled last night in one of your licensed ginshops, by the foul hand of the brute which she calls her husband. What reduced her to that condition? The will of God? No! but the curse of drink. Look at that case of delirium tremens in all its revolting ghastliness. Who reduced the man to this heat of wretchedness? God? No! but his own depravity. Look at that young man yonder dying from the awful Nemesis of his own early vices, his loins full of a sore disease which shall lie down with him in the grave. Who slew all these? God? Nay! but they died of moral suicide the wilful defiance of God's merciful and beneficent laws. While it is our duty to mitigate the awful results, have we no duty also as regards the awful causes? Even mere sanitary duties are potent against the multiplication of disease. Give the people pure air and pure water, and the atmosphere of cities will not be winnowed by the foul wings of the pestilence. Bring greater cleanliness into homes, and before its touch, as before the touch of Christ, fever and cholera will vanish as the "black death" and the leprosy have already fled. But much more: help men to live in temperance, soberness, and chastity, and the legion of evil spirits who batten upon human degradation will sicken, and shriek, and die. To heal disease is Christ's work; but to pull down rotting streets, to provide proper dwellings

for the poor, to minimise cruel temptations, to train children in habits of self-control, to make it easy to do right and difficult to do wrong, to treat vice and foulness as spectres to be exorcised, as monsters to be expelled,—that too is the work of every Christian. By so doing we advance the Kingdom of God. If the task seem hopeless, it is only because we are slothful and selfish. When men become faithful, fearless, loving, Utopia will be but another name for time.

THE CHRIST-LIKE WORK OF THE HOSPITALS.

But that bright day will not be yet. For many a long year, while, step by step, we try to remedy, we must also try to heal. That is the work of these our great hospitals, with their clean bright wards, their faithful medical staff, their devoted nurses, their loving Christian visitors. I know no institutions which the Lord Christ would have more deeply loved. Not a day passes but what deeds are done in them which He would have approved more than 20,000 daily services, more than 500 fasting communions, if they bring forth no fruit of love. To provide the poor worn mother with a room where, skilfully tended and lovingly cared for, she may recover or die in peace; to surround the poor workman, whose limb has been shattered, with such trained ministrations as shall save him from becoming a helpless burden on those whom he best loves; to help the poor lad, maimed by some accident, to bear more easily the anguish of a boyhood which has thus been blighted; to re-illumine the dulled light in the eyes of children, and on their cheeks the faded rose, and where it is beyond us to give back life's lost sunlight to poor sufferers, at least to tinge with the moonlight colourings of resignation the clouds which have darkened our human lives; this truly is an angel's, this truly is a Christlike work. And it is the work of hospitals. We are asked to-day to support them. If we are beneath every appeal but that of selfishness, even on selfish grounds we ought to help them liberally. For if their direct ministrations are mainly for the poor, their resultant blessings flow largely back upon every class alike. It is in them that our surgeons and physicians learn the art of healing. It is in them that our nurses acquire their skill, and pass cheerfully from the dying bed of a great noble to the dying bed of some poor sufferer in Clare-market or Drury-lane. It is through them that there has been so vast a diminution of the annual mortality of London. It was in them that the use of anæsthetics was perfected which exempts our minds from some of their deadliest terrors. It was in them that the antiseptic treatment was developed, which has already saved thousands of lives. It was in them that men have learnt how cholera is caused and typhoid multiplied. If you have done anything for them you have been superabundantly rewarded. Out of 4,000,000 inhabitants of London, 1,000,000 directly received relief from the hospitals this year alone.

NOT A BURDEN BUT A PRIVILEGE.

I would entreat you, then, to regard the opportunity of his day, not as a burden, but as a privilege. How very few, alas! of any congregations are taking any direct personal part in works of good. Ask yourselves, each of you, what you are thus directly doing to alleviate the misery, to elevate the condition, of your brother-men. Multitudes of you, if you be honest, will be forced to admit, "We are doing just nothing outside the circle of our families and the routine by which we earn our daily bread." Well, then, if that be so, you are doubly bound: you are bound by every law, human and Divine, to give to the utmost of your power. Do any of you think that London in this matter is commendably generous? If I am to speak truth, not flattery, I say shamefully the reverse. This wealthiest city in the world—this city, of which the wealth is said annually to increase by £20,000,000—is appealed to by the united voices of every single religious denomination on one Sunday, and it only gives some £30,000—i.e., some seven-hundredth fraction, not by any means of its income, but of its yearly accumulation. Out of our 4,000,000 people, one in every four is directly assisted, and only one in every thousand separately contributes. All classes are to blame. Myriads of the poor, who receive the noble beneficence of hospitals, do not spare for them all their lives long so much as the value of one quart of ale from their monstrous luxury of drink.

WHAT SHALL I SAY OF THE RICH?

And the rich—what shall I say of the rich? I say that there are scores of men in London who could save our hospitals from anxiety almost without feeling it. Look at very recent art sales—£2000 for one dessert service; £1500 for two flowerpots; £3000 for a chimney ornament; £10,000 for two rose-coloured vases; £300 for a single lady's dress; £1000 for the flowers of a single ball. I do not criticise this expenditure; I only say that, if there be in London such a Pactolus of wealth for these gewgaws of silk and of clay, can there be by comparison only a drop or two to heal the bodies, to ameliorate the souls of men? Why should the runnel of Charity dribble on as it does while the full tide of Luxury is still at flood?

"I SAY ALL CLASSES ARE TO BLAME!"

I say all classes are to blame. The working classes, whom it is the abject fashion of the day to fool and to flatter to the top of their bent, are every bit as selfish and every bit as extravagant in their way as the rich are in theirs; and, if it comes to that, the day labourer or the shoeblack, who starves his children and leaves his wife in rags in order to besot his own degradation with beer and gin, is indefinitely more guilty than the millionaire who indulges his taste for jewels or bric-à-brac. I should like to know how many thousands of pounds exchange hands every Derby Day, not only among the rich, but even among schoolboys, and shop-boys, and clerks, and loafing idlers in back slums, who are so ignorant of the whole matter as to be every blackleg's ready dupes. If all this flood of money is forthcoming for the Satanically senseless folly of gambling, is there so little by comparison for worthy and noble purposes? I said that 1,000,000 persons are every year relieved and aided by our London hospitals, and that is a considerable under-statement. Well, if only this million thus directly benefited would but contribute 1s. apiece in gratitude for medical skill, more precious than a king could have purchased a hundred years ago, that shilling apiece would at once produce £50,000, which would not only exceed, but almost double, what London has annually given for her 100 hospitals. Yet, obviously, these shillings are not forthcoming. Were there not ten cleansed? But where are the nine?

FOLLOW IN THE BLESSED MINISTRIES OF MERCY.

The case this year is urgent. These blessed institutions are at this moment £40,000 in debt. Might not, then, some of you who have come to-day meaning to give silver—might you not just as easily, with no real self-denial to yourselves—might you not more conscientiously give gold? Might not some of you who have come with your small coin ready prepared make for once an infinitesmal sacrifice for Christ, and give double or treble or decuple the value of that coin? Will none of you try to-day (were it but for once), with the poor entrusted mammon, to earn something of the true eternal wealth? Do this my friends, and if you do it in a right spirit, and if you leave this church with a deeper desire to follow, in the blessed ministries of mercy, the example of your Saviour Christ, I am sure that your hearts will be all the happier, and your thoughts all the sweeter, when you lay your heads upon your pillows to sleep to-night. I ask you then to do it, I appeal to you all, to the rich, the middle class, the poor, the generous-hearted Americans, and strangers here present. My voice is feeble and insignificant, but may you not hear, even in my voice, the millionfold reverberation of countless pleading agonies,—yea, the cry of charity herself, the voice of your Saviour Christ? To you who know what sickness is, I appeal by the sad fellowship of human pain; to you who know it not, I appeal by your gratitude to God for the priceless boon of health, by the sacred name of those who suffer, by the awful mystery of human anguish, by the withered strength and the throbbing nerve, by your own dear children whom you shelter so tenderly, by those other little ones the shorne lambs of Christ's flock, by the strong man's agony, by the brave man's tears, by the hectic flush upon the young man's cheek, by all the sacredness of human sympathy,—ay, and far more in the name of Him, who dropped the awful plummet of his Godhead into the fathomless abyss of human woe and pain,—for His sake, in His name, I plead with you for this, and for all good works. He that soweth plenteously shall also reap plenteously; or, as it is more forcibly and beautifully in the original and in our Revised Version, "He that soweth with blessings shall reap with blessings."

SERMONS AND ADDRESSES.

ST. PAUL'S CATHEDRAL.

THERE was a large congregation at the morning service in the Cathedral. The sermon was preached by the Rev. Prebendary Billing, rector of Spitalfield, who took for his text 2 Kings v. 3: "And she said unto her mistress, Would God my lord were with the prophet that is in Samaria! for he would recover him of his leprosy." He referred to the applicability of the lesson taught in the text to the present occasion, and observed that there was a deep significance in the association in the Old Testament time of the teacher and healer—the man who was sent as a teacher also found to be a healer. That was anticipatory of the time when the greatest Teacher and Healer should himself come. At the present time we had found the suggestion of the teacher and healer being acted upon. We had now medical missions—men and women who went forth by the practice of the healing art to relieve men from their bodily afflictions and infirmities, and also to induce them to worship Jesus Christ the true Teacher and Healer. The hospitals were the pride of our city, and they enabled, through the ministrations of the chaplain, nursing sisters, and other godly men and women, together with those of the physician and surgeon, a work to be performed which was Christian in the highest and fullest sense of the word, because the work was a work which combined the teacher and healer, and which brought the greatest comfort to the soul, while it ministered comfort, healing, and help to the body. An invitation was now given to all those who under any form worshipped the one true God to unite that day to help to maintain the good and useful work which was carried on in our hospitals. Let them set an example in that metropolitan church of Christian benevolence and Christian charity and gratitude to our Lord Jesus Christ.

The afternoon service was invested with additional interest by the presence, in accordance with annual custom on the first Sunday in the Trinity sittings, of her Majesty's Judges, and of the Lord Mayor, the Sheriffs, and the members of the Corporation of London, all of whom wore their State robes of office. There was a very large congregation. The judges present were—the Lord Chancellor, Lord Justice Fry, Mr. Justice Denman, Mr. Justice Chitty, Mr. Justice North, and Mr. Justice Grantham. With the Lord Mayor and the Sheriffs were Alderman Sir J. Whittaker Ellis and Mr. Alderman Gray, the Recorder, the Common Serjeant, and others of the high officers of the City. The members of the Common Council wore their mazarine gowns, and, like the judges and the civic authorities, carried nosegays. The sermon, which was prefaced by the Bidding Prayer, was preached by the Rev. Henry Scott Holland, M.A., the canon in residence, who took for his text Acts ii. 32 and 33. It was their privilege that day to give evidence that God was still in their midst, and to prove, even to the cynical, that those who loved God could not help loving their brother also.

WESTMINSTER ABBEY.

THE 10 o'clock morning service was attended in State by the Lord Mayor and the Sheriffs of London and Middlesex, and also by the Duke of Westminster as Lord High Steward of Westminster. The sermon was preached by Dean Bradley from the words, "Remember that thou in thy lifetime receivedst thy good things." The preacher urged that the parable of Dives and Lazarus was being enacted in various ways in these days, that he who lived a life of enjoyment and shut his eyes to the misery around him must inevitably suffer "evil things," and that it was not enough to give the crumbs that fell from the tables of the rich, but that the poor must share in their consolations and enjoyments. These considerations were specially applied to the cases of sickness and accidents, and their treatment in hospitals.

The Archbishop of York preached to a large congregation in the evening, on the Divine purpose in the permission of suffering, the completion of that redemption which is the "earnest expectation of the creature." He contrasted the theories of optimists and pessimists, and said there was a third which was often overlooked. Christians seemed to abdicate their power over these questions, and to act as if the Gospel were a message of salvation for another world, whereas it was nothing if it were not redemption for this world. It was not for religious teachers to stand apart and say they had nothing to do with the advancement of men. The Gospel declared the equality of all men long before independent theorists had thought out the doctrine. The Gospel view of equality would quicken the recognition of the claim of the hospitals. It was a great claim shamefully neglected or put aside. We taxed ourselves by Hospital Sunday 6d. in £100 of income, or 1-16th of 1d. in the pound. It was disgraceful—he could not use a milder word—that there should be at this time a talk of throwing the care of the sick and injured on the State, and making that which was the plainest Christian duty a matter of municipal concern. They ought not to allow this. It would be an abdication of their power; it would be a scandal to a Christian country, if they could not by an effort reverse this state of things, and place the hospitals in a condition to do their work completely and efficiently

ST. JUDE'S, SOUTH KENSINGTON.

THE Vicar (Rev. Dr. Forrest) preached from the text, Proverbs xxii 2: "The rich and the poor meet together; the Lord is the maker of them all." After enlarging on the text, the preacher said:—One great mean or instrument of relieving the vast mass of human misery is brought before the people of London to-day, in every church and chapel of the metropolis—viz., the hospitals and medical charities of London. It is very grievous and distressing, and even humiliating, to have to report that there is a deficit in the hospital funds this year of about £40,000. It has been calculated, almost to a certainty, that as many as a million of the population have derived benefit, in one form or another, during the past year; yet this is the unsatisfactory and melancholy account we have to give to the support those splendid institutions receive from the public. It has been felt by those responsible for the management of our hospitals that this state of things should not be permitted to continue, and that a special effort should be made this year to render Hospital Sunday a greater success than it has hitherto been. Accordingly, meetings have been held in various districts of London, and some of the leading men of our time have done their utmost to call attention to the noble cause we, the clergy, are privileged to plead to-day. In addition to this, all the principal newspapers have devoted their space, so valuable at the present time, to give full and detailed reports of these meetings, besides inserting powerful leading articles on the subject. Of one journal I must, in simple justice, make honourable mention. One of the proprietors of THE LANCET contributed £1000 to the Hospital Sunday Fund last year, and has offered to contribute another £1000 should four others subscribe a similar sum. But not content with this, the proprietors of that journal, at considerable cost, have issued 20,000 free supplements of their influential journal in order to disseminate information as to the condition and needs of our hospitals, and especially to furnish all who have to plead the cause to-day with such full knowledge of facts and figures as will enable us to do so effectively. I do not enlarge upon the benefits we ourselves derive from the hospitals. We are often amazed at what modern surgical science can accomplish. Oh, how much do we feel we owe, every one of us, directly or indirectly, for ourselves, or those dear to us, to the noble medical profession! But do we always realize that our physicians and surgeons learn the

practice of their profession in those great schools, the public hospitals; but I do not dwell on this, as it might seem a selfish reason to urge upon you to-day. I prefer to dwell on the incalculable benefits conferred by these blessed institutions on the poor, the suffering, the miserable around us on every side. It has been suggested if only one of the many friends of each of the million patients just referred to would make up his or her mind to give even one shilling to the Hospital Sunday they alone would swell the total by £50,000. The preacher then made an earnest appeal to the immense congregation which filled all parts of the spacious church, referring to their great generosity in past years, and asking them to surpass themselves on the present occasion. The collection amounted to £850 17*s.* 7*d.*, being more than £133 in excess of last year's offertory.

CHAPEL ROYAL, WHITEHALL.

THE sermon in the morning was preached by the Rev. Dr. Momerie, who prefaced an interesting discourse against selfishness with these words: "You have all heard that the London hospitals are sorely in need of increased support. At least double the amount of last year's collections should be contributed to-day in order that these beneficent institutions may continue to perform their work efficiently: £80,000 is wanted, as against £40,000 collected twelve months ago. If every individual would only give double the amount which he contributed last year, the desired result would be attained. The advantages afforded by the hospitals to our poorer brethren, when suffering from disease or stricken down by serious accidents, are so obvious that it is not necessary to dwell upon them. But great as is the good done by the hospitals in the cause of the poor, it does not constitute their sole claim to your support. Those who can afford to pay for the very best medical attendance are also indebted to these public institutions, because the best part of a doctor's education is that which he obtains in the hospital. We ourselves, therefore, are benefited by the hospitals, and in helping to maintain them we are doing an act of justice rather than of charity. I hope, then, you will contribute to-day as generously as you can."

CHAPEL ROYAL, SAVOY.

THE Rev. Henry White preached from Acts iii. 2, and id that the religion of Jesus Christ inaugurated that reign mercy and loving-kindness for the sick and sorrowful which d been foreshadowed and predicted in Hebrew prophecy. he men who scorned the name of religion were not the men hom were due the beneficent enterprises which had soothed healed the hurts of humanity. An undevout philanthro- was rarely to be met with. There was a beautiful expe- ment, by which grains of sand would arrange themselves on glass plate in symmetrical figures under the influence of usical sounds. So the sand-grains of human life were ranged in harmony and beauty when all social life was filled ith the music of Divine sympathy. During the past week uch had been spoken and written to arouse a special interest r the Hospital Sunday this year. The badness of the times, d the pressure upon charity of a long and severe winter, d contributed seriously to cripple the resources of our hos- tals; und political circumstances had removed from London any whose offerings would otherwise have been presented at day. They were therefore asked to make a supreme fort of charity now. Though the Savoy offertory, in pro- rtion to the numbers which the chapel could possibly hold, d ever been one of the largest, if not the very largest in e metropolis, the appeal for redoubled generosity might yet urged. It needed to be remembered that hospitals were equal value to the rich as to the poor, for they were the ining schools for the education of those whose skilful aid might be glad to summon. Indirectly, if not directly, ry member of the community owed an inestimable debt of igation to hospitals. A remembrance of the valuable and paid services which the members of the medical profession dered to our hospitals, and of the devoted and unremune- ed care and kindness of Sisters of Mercy in their holy work of charity, might well awaken and stimulate a bestowment of generous alms to reinstate our hospitals in a condition of full and permanent efficiency.

ST. JUDE'S, DULWICH ROAD.

THE Vicar, the Rev. R. B. Ransford, preached from St. Matthew xi., 2–6., on the temporary failure of the Baptist's faith—his impatience, if not despair. Wickedness and misery rampant. So little being done to remedy. The Saviour's response: an appeal to the good being done, the progress actually made, and the promise of a better time coming. Plenty of suffering and misery now. One million persons seeking medical or surgical relief in one year in London alone! Those who know the poor best, know best their agony. No wonder if their faith fail sometimes. But one million persons relieved in one year in the hospitals of London! How glorious a fulfilment of the promise: "Greater works than I do shall ye do, because I go to the Father." Where scores were healed by Christ, millions are healed to-day in Christian England. What a witness to the blessings of Christianity! And what a strong argument for our support of hospitals! What if the non-worshipping classes leave their share undone? We must fill the gap. One great part of all philanthropy is to remedy the faults of other men.

THE ROYAL HOSPITAL CHAPEL, GREENWICH.

THE Rev. J. B. Harbord, the chaplain of the fleet, preached on the subject of "The Rich Man and Lazarus." These two men are types of the extremes of prosperity and adversity. But the having riches is not in itself a sin, nor the being poor in itself meritorious. Besides the external circumstances of these two, a glimpse is given of their inward character. The rich man's whole life was a sin against God, because he treated the things he possessed as absolutely his own, and lavished them in selfish indulgence, without a thought for the suffering of others at his very door. The other man is called Lazarus, a name signifying "God is my help," showing that in the depth of his misery he trusted in his God. Here is the explanation of what followed. Wealth is a snare and poverty is a trial, and each man shall be judged hereafter according to the manner he has passed through that which has been his lot. The two men both died; to the one death was a happy release, to the other it was parting with all the treasures he possessed. The poor man, whose help was in his god, was now safe in Paradise, associated with the father of the faithful and the blessed angels. The rich, selfish man was alone with his reproaching conscience. He could receive no relief himself, neither could he afford any relief to others; he was a solitary lost soul; no mutual help, no comfort to himself or others, no sympathy with the living or dead, no blessed communion. Our Lord described in the parable two classes—those who have it in their power to help, and those who have need of help—though they do not belong to the extremes of these types. The first lesson is, that we must not treat the things we possess as our own. Our prayer should be, "Lord, what wouldst Thou have me to do with *Thy* good things which Thou hast entrusted to Thy servant?" His answer is given in a form adapted to the circumstances of the great city in which we live: "Support the hospitals, where this help can be given in the most effectual manner." We must not think we can fulfil our duty by casual help at our gates. The true meaning of this parable had its influence on the Holy Church in her organization for the relief of the sick and afflicted. And in the darkest days of the Middle Ages, Christians were not content to leave the sick to chance assistance, and thus in the twelfth century there rose up the Order of the Knights of St. Lazarus. Foregoing selfish luxury, they devoted their lives to relieve the most loathsome forms of malady, and "lazar-houses," or "lazarettoes," were found throughout Christendom. Hospitals of all kinds followed in every Christian city, increasing in usefulness with the development of medical and surgical science—an advance which they themselves materially aided by becoming the great medical schools.

ST. MARY'S, BRYANSTON SQUARE, MARYLEBONE.

THE sermon in the morning was preached by the Rector, Hon. and Rev. Canon Leigh, from the last verse of the Epistle for the day, and the first three verses of the Gospel for the day—*i.e.*, 1 John iv. 21, and St. Luke xvi. 19, 20, 21. The Epistle, he said, taught the first great command, love to God; and also the second, which followed, love to our neighbour for God's sake. In the Gospel we had set before us the terrible consequences of neglecting this Divine command in the parable of Dives and Lazarus. The rich man was punished, not because he was rich, but because of his self-indulgence and the gratification of his own appetites and desires, with little thought of his neighbours' wants. As Christians in a Christian country, it should be the rule of every Christian man and woman to do the work of Christians—to show compassion for the multitude, to help to heal the sick, and to labour in the work of salvation and love. Our noble institutions were symbols of a Christian country. They were unknown before the advent of Christ. We search in vain for remains of them in Athens or Rome, the chief cities of those wonderful countries where civilization reached its highest pitch. With Christianity came the law of self-sacrifice, and from this sprang the establishment of these institutions, which are now to be found in almost every part of the civilized world, and especially in our own land. Such institutions we may consider as sure signs of the prevalence of good laws, sound morals, and a general state of prosperity; and when these institutions began to fail through want of proper support it would be a sure sign of the commencement of the decay of our nation. It was not so much an object that there should be many people as that those there are should live as happily and comfortably as possible, and be relieved of the trials and hardships, the aches and pains, which are incidental to poor suffering humanity. The preacher then quoted THE LANCET to show that such increased liberality was most urgently needed, and that the rich and poor are equally benefited by our hospitals. "There are, no doubt, in this congregation," he said, "some who owe, it may be, their own lives, or perhaps the lives of those who are near and dear to them, to some skilful operation, or treatment successfully carried out, by able practitioners who have attained a degree of efficiency and excellence which never could have been attained except through constant practice in the hospital wards. Why, there is at the present moment, lying in a hospital near here, one of our church officials, who owes her life to the skill of the operation she has undergone. Thirty years ago her case would have been considered hopeless; twenty years ago there would have been great risk as to fatal results of the operation: then they were 20 to 30 per cent., now they are not more than 6 per cent. This is one example out of a great number of the benefits to the community resulting from hospitals, and it is sad to think that, whilst each year the benefits are increasing, the funds required to meet the expenses necessarily incurred are on the decrease.

The Lazaruses are ever with us. God sends them; and as they are to be found at our gates, wan and haggard and full of sores, and disabled through accident or disease, they are our judges: not merely by whether we give, but by how we give and by what we give, they judge us."

THE HOSPITAL CHAPEL (ST. MARY AND ST. THOMAS OF CANTERBURY), ILFORD.

FOUR collections were made, as usual, during the day, for the fund. At the special afternoon service the Chaplain (Rev. A. Ingleby, M.A.) preached. He pointed out the double and treble force of his appeal in an ancient Hospital Chapel dedicated to the same St. Thomas whose shrine at Lambeth had developed into the great St. Thomas's Hospital. He went on to say that if in other places there was a want of enthusiasm for Hospital Sunday, it would be less due to the Church's apathy for the noble work of the profession represented by THE LANCET, than to the apparent indifference of some of the profession for the work of the Church. He said that where, as in the case of the late Dr. Brett, for many years churchwarden of St. Matthias, Stoke Newington, medical men came forward and placed themselves in sympathy with the work of congregations, the latter would never fail to respond with their thousands, if necessary, as they did to the appeals of that pious and philanthropic man.

LEYTONSTONE PARISH CHURCH.

THE Rev. A. Smythe Palmer, of Holy Trinity, Woodford, preached on Christ's cure of the incurable as exemplified in the miracle of St. Luke viii. 43. He observed that Jesus was the ideal of the good physician, never wearied in ministering to men's bodily ailments, and adopting a distinct mode of treatment to each individual patient, according to his varying need or circumstances. It was a fine saying of Cicero's, that "in nothing does man come nearer to God than in giving health to his fellow-men." The preacher referred to an old and well-authenticated record, that the woman with the issue of blood afterwards showed her gratitude for her cure by erecting a statue of bronze commemorative of the event in front of her house at Cæsarea Philippi, which Eusebius saw, and described in the third century. If we ask ourselves, What shall I render unto the Lord for all the benefits He hath done unto me, in preserving me from this disease, or delivering me from that illness? we need not think to prove our gratitude by vowing a costly statue to our Redeemer. One fellow-man raised up from the bed of languishing, the sick man restored to health, the lame made to walk, the deformed made straight, a *living* monument in God's own image raised up—*that* is the best memorial of our thankfulness. In supporting our hospitals we are doing Christ's work for Christ's brethren for Christ's sake. Done to *them*, it is done to *him*.

ROSSLYN HILL CHAPEL, HAMPSTEAD.

THE Rev. Dr. Sadler took as his text Acts xxiv. 17—"I came to bring alms to my nation, and offerings"—and said that there was a sense in which we all were, or ought to be, public men; that is, we have duties to the public, and are not justified in leaving the public welfare to a class. Our larger sympathies, no less than those of a more restricted kind, have a foundation in our nature; and it is the especial work of the religion of Christ, the religion of the Divine Fatherhood, to unite mankind into one great brotherhood, and to give universality to the claims of humanity. Dr. Sadler showed how truly hospitals are entitled to be regarded as national institutions, the benefit of which extends to every member of the community. But the Hospital Sunday Fund has especially in view those who are more liable to disease, and whose sickness is all the harder to bear from the deprivations of poverty. The value of hospitals was illustrated by instances which had come within his own knowledge, not only in connection with disease, but also in cases of accident. In conclusion, the preacher said that if the wisest of mankind cannot explain the mystery of suffering, all of us know what to *do* with suffering—bear it as patiently as we can, so far as it is irremediable, and alleviate it, as far as we can, where we find it in others. The collection amounted to £77 12*s.* 9*d.*

ST. MARY BOLTONS, SOUTH KENSINGTON.

THE Rev. G. W. Mackie, B.A., B.Sc., Lond., took as his text 1 John iv. 21—"This commandment have we from him, that he who loveth God love his brother also"—and urged the claims which hospitals have on our sympathy and on our purse, upon the grounds of (1) Christian duty, (2) an urgent need, (3) self-interest. The Epistle for the day dwelt upon the vital importance of love of the brethren, which was different from natural affection, inasmuch as it embraced all mankind. The Gospel, which was in the words of Christ himself, gave an awful example of the result of a life of selfishness and indifference to the wants of others: Dives, rolling in wealth, caring not for the sick Lazarus—living in the conviction that it was no concern of his—realizing only

too late that this indifference had been one of the chief causes which had brought him to "this place of torment." The preacher next dwelt upon the well-known facts of the case. All the hospitals were in debt, or at least in difficulties. Those who professed to be constrained by love of Christ ought to be the foremost in setting a good example in this matter. How much depended upon this fund was shown by the fact that only one in two had contributed to the hospitals (apart from the Hospital Sunday Fund)—*i.e.*, in a parish such as their own, of some 4,000 people, rich and poor, young and old, it might be possible to find ten people who had stretched out a helping hand. Doubtless the poor were most directly benefited. Those only who worked among them were able justly to estimate the good the hospitals did for them; but all who had read it must have been touched with the cry of the weak-minded girl in "Little Dorrit"—"Make him have hospitals; they are so heavenly." If heaven means rest, quiet, peace, and loving sympathy, there are thousands who never have, never will taste, these things unless within the walls of a hospital; no wonder, then, hospitals seem to them "heavenly." But the rich were benefited quite as much as the poor, though indirectly. It was the hospitals alone that could train nurses and educate medical men, upon whose care and skill we all, under God, may be dependent for our very lives. It was the hospitals which were the centres of medical advance and of medical science.

PARK CHAPEL, CAMDEN TOWN, N.W.

THE Rev. S. D. Hillman, of Ilkley, Yorkshire, preached in the morning from Romans xv. 1–3, expounding and enforcing the principle contained in the verses chosen, of the strong ministering to the feeble. It was shown that this principle, so frequently reiterated in Scripture, has its application to every age and to all the relationships of human life. Turning from the principle to the pattern, Mr. Hillman dwelt upon the case of "The man Christ Jesus," as furnishing a beautiful illustrative example of the practical exemplification of this teaching. St. Paul might legitimately have referred to his own personal history in this connection, since his career furnishes a striking example of a man strong in faith, hope, love, and zeal, bearing the infirmities of the weak and not pleasing himself. "To the weak he became as weak, that he might gain the weak." "He sought not his own profit, but the profit of the many, that they might be saved." When thinking of the duty of the strong to seek, to comfort, and help the weak, St. Paul's thoughts instinctively turned to the most illustrious example of the exercise of such self-denial and consecration, and his enthusiastic admiration for the character of the great Exemplar found expression in the utterance "For even Christ pleased not himself." The whole life of Christ was one continued exemplification of the prophecy, "Himself took our infirmities, and bore our sicknesses;" and His followers best represent Him when, in His own spirit, they lovingly care for the suffering and sorrowing.

At the evening service Mr. Hillman preached from Hebrews xiii. 8—"Jesus Christ, the same yesterday, and to-day, and for ever"—and in the course of his sermon gave special prominence to the thought of the immutability of Christ as sustaining His servants amidst the adverse influences and the darker experiences of their life.

ECCLESTON SQUARE CONGREGATIONAL CHURCH, BELGRAVE ROAD, S.W.

THE pastor, the Rev. J. Hiles Hitchens, D.D., took for his text Zechariah vii. 9, "Show mercy and compassion every man to his brother." Dr. Hitchens began his discourse by remarking that "a heathen moralist gave as his advice, *Bene velle omnibus, bene facere amicis*—'wish well to all; do good only to friends.' But Godlike sympathy scorns such limitations. It does not wait to recognise in the person of the sufferer a friend, a relative, or even a fellow-citizen. It limits not its range by thoughts of country, class, or creed. It looks upon man as *man*. It embraces all the human race in the arms of its brotherhood. It forbids a man being his own Alpha and Omega. It cannot sit calmly at any banquet while the wan face of the hunger-bitten looks in at the window. It cannot sleep in any man's Gethsemane. It places the man in the very position of the afflicted brother, and makes him mental partaker of his lot. Thus the strong sympathises with the weak, the rich with the poor, the free with the captive, the healthy with the sick, the successful with the unfortunate, the living with the dying. This is true compassion; as the word etymologically expresses, it is suffering *with* another:

> 'Compassion proper to mankind appears;
> Which nature witnessed when she lent us tears.'"

Dr. Hitchens then proceeded to show how this fellow-feeling was manifested in the history of the Old Testament saints; how it was exhibited in perfection in the life and labours of Christ; and how it was cultivated by the early Christians. Quotations from the satirical Lucian, and Julian the Apostate, were given to prove how active the early followers of Jesus were in aiding the sick and poor. The duty and privilege of still cultivating practical Christian sympathy was then enlarged upon. The efforts being made to set class against class were severely denounced; and Judge Talfourd's last words were quoted: "If I were asked what is the great want of English society so as to mingle class with class, I should say in one word, The want is the want of sympathy."

THE CHURCH OF NOTRE DAME DE FRANCE, LEICESTER SQUARE.

THE Rev. L. Thomas made an appeal to his French congregation on behalf of the collection of the day. The preacher urged upon his people to contribute to the Hospital Sunday Fund on the ground (1) of Christian *charity*, inasmuch as their co-operation was requested in favour of the poor and the sick—hospitals are indeed numerous in London, but still not sufficiently so, considering the number of necessitous cases; (2) on the ground of *justice*, inasmuch as many have found, or may find, themselves in the necessity of recurring to the care bestowed in hospitals; (3) from *gratitude*, as many persons of French nationality, though a French hospital exists, are received in those charitable institutions, and, although foreigners, experienced great kindness and consideration on the part of the authorities, surgeons and nurses. Mention was made of the very striking instance, not only of the free access of the French Catholic priest allowed in behalf of a dying fellow-countryman, but also of the promptitude with which he is summoned when the condition of the sick person requires the presence of a priest of his nation. So, the other day, one of the missionaries of Notre Dame de France was called in great haste to attend to a dying Frenchman, a cab being kindly provided for his conveyance to the hospital; and the charitable soul who secured the ministry of the French Catholic priest was one of the resident surgeons of the English hospital which had afforded shelter to the sick foreigner. Every member of the congregation was pressed to act the part of the Good Samaritan towards our suffering brethren, and thus to follow in the footsteps of our Divine Master.

METROPOLITAN TABERNACLE.

MR. SPURGEON took for his text Luke i. 77-79, and concluded as follows:—"There is not a man here to-day who may not himself be in the hospital to-morrow. I ask every man and woman here to-day to give to the common stock for all who need it. The claims upon these establishments are very urgent—so much so that many of them have been obliged to meet their current expenses by the sale of their funded property. I am often inclined to think that the Government ought to take the management of these establishments into its own control, but I am afraid that they would not be managed as well as they now are. The amount of their income should be double what it is now. How many cases have come before each of us where individuals must have died but for the care bestowed upon them in the hospital? This is not a day for small contributions from wealthy people.

Especially is this the day for the pence of the poor. The Lord will accept their contributions even as the widow's mite was accepted.

ISLINGTON PRESBYTERIAN CHURCH.

IN the afternoon Dr. Davidson addressed upwards of 2000 persons at the Agricultural Hall, Islington, on the claims of the Hospital Sunday Fund. Taking for his text Psalm xli. 1, "Blessed is he that considereth the poor," he showed that true Christian charity must be discriminate, and that if the money that was bestowed on street beggars and on unknown applicants at the door were devoted to the coffers of this fund, a great deal more of real good would be effected.

HAMBRO' SYNAGOGUE.

THE Rev. B. Spiers preached in this synagogue last Saturday in aid of the Hospital Fund. He preached on the lesson for the day, Numbers xv. 1. Having pointed out the evil consequences arising from blind ambition, selfishness, and arrogance, so graphically portrayed in the history of the ungodly strife waged by Korah and his associates, the preacher said: "Are not the opposite duties of liberality, unselfishness, and generosity especially commended to us by this same history? And at this time more particularly, when collections are being made on behalf of the metropolitan hospitals and dispensaries, we are forcibly reminded of our obligations in this respect. We should show that although we are separated from those who differ from us in religion and nationality, we, on the other hand, do not stand apart from the rest of our fellow-citizens in matters of common humanity, the alleviation of common distress and suffering. The excellent hospitals in this vast metropolis, in which the best medical and surgical skill, the most finished appliances, the most approved methods of treatment are readily and freely afforded —these noble institutions are sorely in want of funds to carry on their laudable work, and require our generous and liberal support. Shall we stand aloof, and not give our ready assistance where it is so much needed? Shall we see our fellow-creatures suffering, and not endeavour to alleviate their pains? We all know that every human being, rich or poor, strong or feeble, is liable to be stricken down by illness or accident, and when such does occur, and the suffering person is conveyed to one of these invaluable institutions of medical skill and kindness, who can tell the sense of relief experienced both by the patient, and those near and dear to him, when they know and feel that everything which medical science can suggest is being done for the sufferer. There cannot be a more godly act than healing the sick, there cannot be a greater charity than helping to alleviate and to cure disease, and to soothe the sufferings incident to life; there cannot be a more sacred duty than to succour the afflicted poor. And the sages of the Talmud say: "The healing of the sick is so meritorious an act, that whosoever practises it receives his rich reward in this world, and may confidently look forward to eternal bliss in the next."

ST. MARY'S, ENFIELD.

THE sermon in the evening was preached by the Rev. J. Grant Mills, Hospitaller of St. Thomas's Hospital, who took his text from the Epistle of the day (John iv. 8: "God is love"). With reference to the special subject of the day—hospitals—he said, that he had no hesitation in making a strong appeal for help, as he himself was connected with a hospital which had been endowed by the piety and benevolence of our forefathers, and which did not therefore share in the collections of Hospital Sunday. This consideration made him all the more willing and ready to plead on behalf of those hospitals not so happily circumstanced, which were almost entirely dependent upon voluntary offerings. He said that the editor of THE LANCET had done good service, for which they owed him a debt of gratitude in publishing a summary of the work done, and the money expended and received by those hospitals for whom an appeal was made that day. He must confess that the reading of that summary to them made him ashamed of the rich in London. Was it not a scandal that whilst hundreds, nay thousands, were constantly expended on *bric-à-brac*, old china, and so on, there should be a deficit of £40,000 on institutions which were fulfilling Christ's command: "Heal the sick." Was it not a scandal that £11,000,000 could be obtained by a Prime Minister without a dissentient voice, and as the result of one speech, and that the income of these hospitals for which he pleaded should be less than half a million, and that there should be £40,000 deficit. It ought to make people blush. Why, if for no higher reason, they ought to support hospitals for self-interest's sake. He himself lived and had for some years lived in a London hospital, and he could tell them that it would be a poor look out for them in time of illness were it not for the nursing and experience received and gained by our doctors and nurses in the wards of the hospital. What made it possible for them to have the services of skilled surgeons and physicians in their own homes? The hospitals. What made it possible for them to have the services of skilled professional nurses? The hospitals. Well, then, for self-interest's sake support the hospitals. This was low ground, he would like to lift it up. Support them because it was Christlike to heal the sick. These institutions were a testimony to the power of Christianity. There were ways, Mr. Mills pointed out, in which they could help in preventing sickness and disease and its transmission. There were many preventible accidents and diseases due to impurity, intemperance and overcrowding. Let them apply themselves to the removal of these fruitful causes of disease, and they would be helping the hospitals in a very practical way. Their principal thought, however, that day was the collection of money. If we loved God, who is love, because He first loved us; then that love would manifest itself in love to the brethren, and love shown to them was love shown to Christ, who had said, "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto Me."

BAYSWATER SYNAGOGUE.

THE Rev. Dr. Hermann Adler, Delegate Chief Rabbi, took as the text Job xxx. 25: "Did not I weep for him that was in trouble? Was not my soul grieved for the poor?" He dilated upon the importance of practical sympathy, and he characterized each efficient hospital as a true People's Palace. He paid a glowing tribute to the services rendered by the public press this year, and especially by THE LANCET, in diffusing accurate knowledge respecting the medical charities and stimulating the generosity of the community.

ST. LUKE'S, WEST HOLLOWAY.

THE sermons at this church were preached by the Vicar, the Rev. Richard Glover, M.A., from Isaiah xxxiii. 24. He descanted on the many ways in which *sickness is overruled for good*, and amongst them on the effect produced on those who are the mere *beholders* of suffering:—"How much wholesome thought is occasioned by the mere sight of suffering, or by the knowledge of the suffering that exists? The very sight of suffering tends to make the worst, for the time, sober and thoughtful, and to do kind acts that they never might do otherwise, and in this way tends to humanize even the bad. But how salutary the effects on the good! How it draws out their pity, their sympathy, and all their kindly qualities! And what a benefit to them is the fact that it does! See what an occasion sickness is of drawing out and developing medical skill and science, and all the humanities that are connected with the surgeon's and the nurse's care. Then think, finally, of the way in which it develops and exercises benevolence in the world, in regard, for example, to Hospital Sunday. In every Christian city the hospital is erected and maintained, and think of the amount of wholesome sympathy and benevolence that all this evokes, and of the wholesome effect of all that even on those who show it. And thus, through the mercy of God, the very curse is turned into a blessing, and good comes out of evil. Yet an evil,

nevertheless, sickness is. It is no creation of God, but a creation of sin; and in that world or state where there is no sin "the inhabitant shall not say, I am sick."

CHEAPSIDE, MERCERS CHAPEL.—Rev. Arthur Veysey, Chaplain to the Company, on "Dives and Lazarus." Collection £13.

ISLINGTON, AGRICULTURAL HALL.—Rev. Dr. Thain Davidson, to congregation of upwards of 2000 persons. Psalm xli. 1.

HOSPITALS WEEK MEETINGS.

MEETING AT KENSINGTON TOWN HALL.

THE third district meeting was held at the Town Hall, Kensington, on Wednesday afternoon. The chair was taken by the Duke of Norfolk, who was supported by Lord Cadogan, Mr. W. H. Smith, M.P., Sir Sydney Waterlow, M.P., Sir William Mac Cormac, Rev. Dr. Finch, and Mr. H. C. Burdett. Letters of apology were read from the Dean of Westminster, Lord Hartington, Canon Fleming, the Hon. F. Fortescue, and others.

The DUKE OF NORFOLK, in opening the proceedings, said all present must know the importance of the work which they were met to put forward, and also that it had not heretofore met with the success which its importance deserved, and therefore those who had energetically undertaken to foster its operations had thought it well to make a great effort to stir up public opinion throughout the metropolis in support of the hospitals. It was an unfortunate occurrence that the week which had been chosen for the advocacy of this crusade should coincide with a week in which the whole country was taken up with preparations for the forthcoming elections; but this ought to stir them up to be more eager to support the cause of the sick poor of London rather than to forget them at this crisis (hear, hear). Throughout the country men were doing their best to forward one cause which they believed to be the best for the people at large, but they might be quite sure that whatever mistakes individuals or parties might make in political warfare, they would make no mistake at all in doing the best to succour the sick poor. It was a cause they would always have before them, for do what they might by generous assistance, and however progressive the science might be which it was their object to foster and extend, they might be quite sure that the pleadings of suffering humanity would never be silenced. But while they could not take away from them that melancholy and continuous appeal, they could at all events draw great good from those evils by showing to those who suffered that they were not forgotten in their sufferings. He urged them to do everything they could in support of this great cause, to determine never to forget its importance, and the lamentable fact that it had not hitherto met with that support which it so richly deserved.

Mr. W. H. SMITH, M.P., moved the first resolution: "That this meeting pledges itself to use every endeavour to arouse the inhabitants of this district of London to the importance of maintaining the hospitals and medical charities in the utmost efficiency; and, in furtherance of this object, it urges the clergy and ministers of religion to make an earnest appeal to the people to so increase their contributions on Hospital Sunday as to secure that the whole sum collected shall not be less than £80,000." He said the concluding paragraph of the resolution was a measure of the magnitude of the effort which would be required next Sunday. He spoke of the necessity of arousing the attention of the public of London to this great want, because a vast number of the inhabitants of the metropolis, who were in comparatively easy circumstances, were unaware of the great necessity and want existing at their doors, and were not capable of being brought to realize their duty under the circumstances in which they were placed (hear, hear). A double appeal was made—an appeal to those who were present, and also an appeal to the clergy of that prosperous and wealthy district, to use the great influence which undoubtedly they possessed, and, as a rule, worthily exercised, to bring before their people one of the most pressing Christian duties which it was possible for human beings to be called upon to discharge. What was it they were asked to do? It was to take the best means in their power to secure that their neighbours and fellow-subjects should have the best possible attention and relief in time of sickness, when they were unable to help themselves. The hospital was the sick-room in the home of the poor man; it was that which he could not provide for himself, and as he could not provide it for himself, it was the duty of others in better positions in life to do it for him. He knew there were persons who said that this was a duty which might fitly be undertaken by the State, and not a duty which fell upon individuals. He should be exceedingly sorry if that were at all a common feeling. No greater misfortune could happen to the cultivation of the science of medicine, to the training of the future doctors and surgeons, than that the voluntary hospital should cease to maintain the position which it had held in the metropolis and throughout England during the past half-century (cheers). However excellent a public institution might be which was maintained by taxes or rates, there was something wanting in it which was found in a voluntary hospital—the personal interest, sympathy, and care—the deep anxiety to relieve suffering. There was a Christian feeling pervading the work of the voluntary hospital day by day—the desire of self-sacrifice, the pleasure of doing good; and however excellent a rate-supported institution might be, everyone there was paid to do his duty, and they could not find the amount of self-devotion and earnestness in the work, which was found in those who devoted themselves to doing good for the love of it (applause). On that account it would be a very great misfortune indeed if one after another of these national institutions must be closed because those who possessed the money had not the consciousness that it was their duty to assist those who devoted themselves to this work. Looking to the great benefits which the hospitals conferred upon society at large, he urged their claims upon all those who had it in their power to aid in their support.

Sir SYDNEY WATERLOW said: Having as Lord Mayor in 1873 established the Hospital Sunday Fund in London, and having been vice-president ever since that period, it was very gratifying to him to find that from year to year public interest in the movement continued to be enlisted to a larger and larger extent. In the beginning they had no doubt many difficulties to contend with; but thirteen years had satisfied the public that if they had the means they could not do better than contribute to the Hospital Sunday Fund, and for this reason, that no grant was made to any hospital or to any dispensary until the accounts of the past three years had been sent in to the committee, and so carefully analysed and dissected as to enable the committee to determine not only that they needed help, but that they deserved it, because they did their work well (applause). The grants recommended by the committee were always made upon the basis of the needs of the institution. One great point in

favour of this fund was, that whether by annual subscriptions, or dinners, or any of the other various methods adopted, in no case was the collection made at such a small cost. The whole of the money contributed, with the exception of three per cent., which was the cost of collection, went direct to the funds of the hospitals and dispensaries. They had no rent, rates, or taxes to pay, for through the kindness of each successive Lord Mayor they were able to carry on the whole of the business at the Mansion House. They had collected on an average during the last thirteen years between £28,000 and £30,000 on Hospital Sunday, from about 1500 congregations; but that was not anything like the sum they ought to collect or would collect if the question was fairly and clearly understood by the public of that great metropolis (applause). £34,000 only enabled them to contribute about one-eighth of what was absolutely necessary for carrying on these hospitals and dispensaries. The number of patients coming to the London hospitals continually increased, not merely in proportion to the ratio of the population, but as they increased the facility of communication between the metropolis and large towns in the country districts, patients who could not be as efficiently and carefully dealt with in the country were continually sent up to London in larger and larger numbers. He hoped, therefore, that all provincial visitors to London, of whom there were so many at this time of the year, would give a contribution in recognition of the use made of the London hospitals by the country people. He called attention to a statement in the *Daily Telegraph* that morning, challenging the idea that all the great London hospitals—Guy's, St. Thomas's, and Bartholomew's—were in debt. As treasurer of St. Bartholomew's, he was happy to state that it was not in debt; but all these hospitals had been seriously crippled, and all the others, without exception, were actually in debt, owing to the serious diminution of their incomes, and in many cases hospitals had had to draw very largely upon their capital. He was very glad these meetings were being held, and felt sure that it was only necessary to bring the facts before the public, and to make them clearly understand the facts of the case, in order to secure a very largely increased support. He added that none of the funds collected on Hospital Sunday would go to Bartholomew's, St. Thomas's, or Guy's. Those hospitals had not yet applied to be on the fund, though the time might come when they would have to do so.

The resolution was unanimously agreed to.

The EARL OF CADOGAN moved: "That this meeting regrets to learn that the expenditure of the hospitals and medical charities of this district in the year 1885 exceeded the charitable income by £20,000, and pledges itself to increased exertion with the view of preventing any like deficiency during the year." He said that hospitals really covered nearly all the aims and objects of really true charity. It had been said that poverty leads to sickness, and that was no doubt true; but it was also equally true that sickness itself very often led to poverty. By the means of hospitals those who, if their sickness had not been cured, would have been plunged into want and misery, were saved to live lives of usefulness and to be able to support their families. That being so, and the advantage of hospitals being so patent to all, how was it that even in that district the expenditure had so largely exceeded the income? That question required an answer, and the best answer which could be given would be that year by year they should endeavour to supply that want, until at last it should be found that the annual income of these charities was equal to their expenditure.

Sir WILLIAM MAC CORMAC seconded the resolution, and said he was in some sense an outsider, because he belonged to one of those great hospitals (St. Thomas's) which were outside the sphere of the operations of this fund. Sir Sydney Waterlow had told them, with regard to St. Thomas's, that it was restricted in the usefulness it might otherwise be doing, by the diminution of its income in recent years. It was quite true that these great hospitals had suffered with the others. Nothing more astonishing had come out in the inquiry that had resulted from the institution of these meetings, than the fact of the very limited number of persons who subscribed to the London hospitals. There were some hundreds of them, and yet, as he was informed, but one person in every hundred was a subscriber to these charitable institutions. Surely there must be some reason for this that was not apparent on the surface. He could scarcely imagine that anyone understanding and knowing something of the work done in those institutions could hesitate to respond to the call which had now been made upon them. In the hospital to which he belonged there was a large number of beds occupied by sick and sorely suffering persons, but not merely were the beds occupied, but every day and every week hundreds upon hundreds came to that and other hospitals with many ailments, for which they could be treated as out-patients. The benefits of the out-patient department were perhaps not sufficiently realised, but they were not less great than the work done within the hospital wards themselves. Of one thing he was sure, namely, that hospitals were a necessity of their social organization. They would never be able to do without them, and if the community at large did not support them, then the State must step in and do it. That no doubt would be a disaster. He knew from personal experience what the rate and State supported hospitals were in France, Germany, and Austria, and he could assure them that the sympathy there afforded was not the same kind of sympathy with that given in the voluntary hospitals of this country. Patients in foreign hospitals were looked upon in some instances as subjects for scientific consideration; whereas, as had been truly said by a speaker at one of the former meetings, each one of the patients in an English hospital, was regarded as everyone could wish to be regarded if in a similar condition, and nothing was done that would not be freely done to those who might be very near and dear to the attending physicians and surgeons themselves.

The resolution was adopted.

On the motion of Mr. H. C. Burdett, seconded by the Rev. Dr. Finch, a cordial vote of thanks was accorded to the speakers and to the Duke of Norfolk for presiding, and the proceedings terminated.

MEETING AT ST. ANDREW'S HALL, NEWMAN-STREET.

THE fourth District meeting was held at St. Andrew's Hall, Newman-street, on Thursday evening, the 24th ult., under the presidency of the Earl of Northbrook, who was supported by Lord C. Beresford, M.P., Mr. Bauman, M.P., Mr. Seager Hunt, M.P., Sir Julian Goldsmid, Bart., M.P., Sir Risdon Bennett, F.R.S., Mr. J. McMillan, Mr. H. C. Burdett, Rev. Dr. Finch, Mr. H. N. Custance, &c. There was a very good attendance, including many tradesmen and working men.

Lord NORTHBROOK, in stating the objects of the meeting, claimed that no provision could be made by any man, however wealthy he might be, with respect to accidents, at all approaching that made in the hospitals, and the same thing might be said with regard to the vast majority of the population in reference to disease. There had been 59,000 in-patients, and 941,000 out-patients, treated in those institutions in the course of the last year (applause), and the cost of dealing with this vast mass of human misery was £490,000. The annual income, he was sorry to say, was only £450,000, leaving a deficit of £40,000 on the year 1885 alone; and an additional sum of £40,000, making £80,000 in all, was required to place these institutions in a thoroughly satisfactory and efficient condition. So that, although they might congratulate themselves on the large development and great efficiency of these hospitals, they must also look in the face the necessity for increasing the amount of annual contribution, in order to maintain that efficiency. It was for that object that this movement had been inaugurated, and it was one which must commend itself to all who took an interest in their fellow-creatures. No doubt just now times were hard on everybody, and he did not know that those interested in hospitals had any real cause to complain of the manner in which the middle classes of the country helped to support them. It was not their wish to throw blame upon any one class; what they wanted was to call the attention of everyone to the necessity of hospitals, and

by more earnest effort to increase the channels of contribution to those institutions. The way to keep up the funds of a charity was to encourage as much as possible small contributions. The mechanics and artisans were in many cases those who got the most advantage from the hospitals, especially with respect to accident wards; and he was quite sure that if efforts were organised to obtain contributions in their great manufactories and workshops, something might be done to increase this fund. Referring to that particular district, he said the finances of their hospitals were rather worse than they should be as compared with those of the whole area of the metropolis, the deficit being no less than £18,000 on last years working alone.

Lord CHARLES BERESFORD, M.P., moved the first resolution, pledging the meeting to use every endeavour to arouse the inhabitants of the district to the importance of maintaining the hospitals and medical charities in the utmost efficiency, and urging the clergy and ministers of religion to make an earnest appeal to the people, so that the whole sum collected on Hospital Sunday should not be less than £80,000. He said of all the forms of charity to which their great and generous-hearted nation subscribed, there was no form so grand as that which gives money towards the hospitals. He showed that while in 1873, the first year in which the Hospital Sunday collection was taken, £27,370 was collected and divided among fifty-four hospitals and fifty-three dispensaries; in 1885 the amount collected (£52,000) was divided among 140 hospitals and dispensaries, so that their proportionate share was much diminished. He urged that special attention should be directed to the Hospital Saturday Fund, as it seemed capable of very great expansion with a more extended organisation. A Frenchman had once said, on learning that the English hospitals were voluntarily supported, that that fact ought to be inscribed outside the building in letters of gold, and he agreed with the Frenchman. (Applause.)

Mr. BAUMAN, M.P., in seconding the resolution, said he had lately taken a deeper interest in the London hospitals from the conviction that if they were going to have two general elections a year he should very shortly become an inmate of one of those hospitals. (Laughter and applause.) It would be interesting to stop and ask the average Londoner—the man in the white hat who rides on the knifeboard of the omnibus, and who Lord Palmerston used to say you must question if you want to get at the average mind—how he thought the 104 hospitals in London, of which we are all so justly proud, have been founded, and how they are maintained? Judging from the amount of contributions traceable to the inhabitants of the metropolis, the average Londoner apparently thought that hospitals grew by some unaided operation of nature, for in no other way was it possible to explain the fact that in the richest city of the world, whose mere bricks and mortar were valued at something over thirty millions sterling, the annual average sum collected for hospitals on Hospital Sunday varied from £28,000 to £34,000. When they came to consider the amount of money that was spent—he supposed he must not say wasted—on politics and pleasure, they would agree with him that that was a ridiculously small result. (Applause.) It only amounted to £1 per thousand people—at least so he was told by an arithmetician in *The Times*, and if they were very good arithmeticians they could find out for themselves what an infinitesimal fraction of a farthing that was per head of the population. He confessed that the sum was too difficult for him. He was bound to add, for the credit of Londoners, his conviction that their omission was one more of ignorance than of ill-will; if they did not open their purse-strings as liberally as they might and ought, it was not because they undervalued the good work being done by the hospitals, nor was it because they failed to appeciate the absolute necessity of their existence. They had hitherto laboured under a hazy and comfortable delusion that there were plenty of rich people who were always dying and leaving money to hospitals. The facts brought to light during the past week must have opened their eyes rather rudely. It was, he believed, too true that most hospitals lived, like Mr. Micawber, in a state of perennial expectation that something would turn up (laughter) in the shape of a windfall. But whether it was due to the depression of trade or to the development of medical science, the fact remained that rich people no longer die (laughter), or rather, he ought to say, people no longer die rich in these days. It was to supplement and compensate this falling off in benevolent bequests that this strong, earnest, and, he hoped, successful attempt was being made to stir up not only the consciences and compassion but also the ordinary prudence of Londoners. For, after all, it is a matter of common prudence to keep our hospitals going. It is only in the houses of the comparatively rich, only in the houses of the few that there is adequate accommodation for the sick and wounded or invalid. Hospitals, therefore, seemed to him to be as much necessaries of our modern life as gas, water, and drainage, for which we all pay such heavy taxes so cheerfully and so ungrudgingly. He hoped that this year the amount of contributions to the hospitals would double that of the previous year. (Applause.)

The resolution was carried by acclamation.

Sir RISDON BENNETT, in moving the second resolution, "That this meeting regrets to learn that the expenditure of the hospitals and medical charities of this district in the year 1885 exceeded the income by £18,000, and pledges itself to increased exertion with the view of preventing any like deficiency during the current year," said there was hardly anything more conducive to the interests of their country as a great commercial country than the support of the various institutions by means of which labour and all its adjuncts were carried on so much more efficiently than they could be without those aids. It was the greatest glory of this country that charitable institutions were voluntarily supported. There was no country in the world that could make such a splendid display of hospitals and benevolent institutions established by the freewill offerings of the people, without any aid from the Government, and one of the most striking features in the development of the colonies was their imitation of the mother country in this respect. Hospitals were institutions by which the public at large were benefited indirectly as much as those who were assisted there, because it was in the hospitals alone that students could gain the skill which resulted from personal observation of disease on a large scale, and which they were afterwards able to put into practice in their professional life. He was sure that nothing would tend so much to secure the success of this movement as to make the action of the hospitals more generally known. (Applause.)

Mr. SRAGER HUNT, M.P., seconded the resolution. He said that, notwithstanding the immense amount of relief afforded, only £6000 had been collected in that rich district last year. If every one of the patients attended to had subscribed 1*s.* on leaving the hospital an additional income of £8500 would have been raised. If the cost of maintenance were put upon the State, the poor would feel the additional burden, while the rich would be relieved.

Mr. H. C. BURDETT supported the resolution, and said the deficiency was not £18,100 but £22,500, because a sum of £4400 in connexion with some extra new buildings of the Middlesex Hospital had been accidentally omitted. They had heard from Sir Risdon Bennett and others that were it not for hospitals they would have no doctors; but it was also the fact that but for these institutions they could have no trained nurses and no skilled nursing. THE LANCET had sent a special commissioner through all the hospitals of London, and after spending two months in that work he came back and said, "I will tell you why the hospitals want funds. It is a very simple matter. It is because the people do not know what the hospitals are doing. If the people knew what was done in the hospitals they would not want money, and the managers would probably have more money than they knew what to do with." Applying that experience, it was hoped that this Hospitals Week might not be a transitory movement, but that it might take root and flourish and become permanent. He suggested the formation of a Hospital Society in every parish, which might become an organisation for the relief of every kind of human suffering, and also keep alive public interest in this great question.

The resolution was carried unanimously.

On the motion of Mr. J. McMillan, seconded by the Rev. Canon Barker, a vote of thanks was passed by acclamation to Lord Northbrook for his kindness in presiding.

THE FIFTH DISTRICT MEETING.

THE fifth district meeting was held in the Highbury Athenæum on Friday, under the presidency of the Duke of Westminster. The Duchess of Westminster was also present. In opening the proceedings,

The Duke of WESTMINSTER said the object of the meeting, like that of its predecessors, was to awaken the public, especially through the agency of the press, to an interest in the Hospital Fund. A great debt of gratitude was due to the press for its efforts in the cause, without which, indeed, the promoters of the movement would be absolutely powerless. The coming election would probably distract attention from the movement, and the prevailing agricultural and commercial depression would also act prejudicially against it. In London too, from its vast size, there was a want of local feeling and interest; and hence the subdivision of effort that had been made during the week. The matter was one affecting rich and poor alike. To the poor man it was of the utmost importance that his sickness should receive prompt attention, and he could nowhere receive such effective treatment as in a London hospital. The rich also were benefited by the enlarged experience gained in hospitals by those who attended their families. Hospitals were not so liable to abuse as many other charities, and there was no object to which public charity could be so fitly directed. The support of the hospitals fell at present on a very limited number of individuals. The subscribers numbered only 40,000 persons out of 4,000,000. Surely the burden ought to fall on a wider area. The amount required next Sunday was said to be £80,000; the amount hitherto collected was less than half that amount. Besides the general wants of maintenance, there were special wants to be met in the No. 5 district. University College Hospital required enlargement and a great deal of rebuilding, entailing a large outlay. The Soho Hospital for Women also required enlargement, so as to accommodate a larger number of patients. A site had been selected for the North London Central Hospital, but sufficient funds had not been received to enable the committee to begin building. A great deal of interest had been taken in another matter which was in one sense connected with hospitals. There was a Bill in Parliament for acquiring the open space known as Parliament-hill, near Hampstead, and, if that addition to the Heath could be made, probably less funds would be needed for the North London Hospital, and the health of the metropolis would be largely promoted.

Sir SYDNEY WATERLOW moved the first resolution, pledging the meeting to use their best exertions to promote the efficiency of the London hospitals, and urging ministers of religion to make an earnest appeal for increased contributions, so that the whole sum collected might not be less than £80,000. He said that no money was collected for charitable purposes in London at so small an expense as that collected for the hospitals. None of it was wasted in transit, but went direct to the object for which it was given. Grants were made by the Hospital Fund to 115 institutions, according to their needs and merits, which were inquired into with the greatest care. The amount collected in 1885 was £34,320, contributed mainly in 1597 places of worship. In a rich place like London that was not an adequate amount, and he hoped it would be largely increased. Even if the £80,000 asked for by the Duke of Westminster were given it would only provide about one-fifth of the total amount that had to be collected. The wants of the hospitals were constantly increasing, not only for the inhabitants of London, but to meet the applications often made from the provinces. Increased expenses had to be met for the improved nursing and the additional cleanliness attending it, for surgical appliances, and other demands.

Mr. C. LAMBERT, in seconding the resolution, urged the claims of the hospitals in the district, and expressed a hope that the utmost endeavours would be made to meet their pressing demands.

The resolution was unanimously adopted.

Mr. INCE, M.P., moved: "That this meeting regrets to learn that the expenditure of the hospitals and medical charities of this district in the year 1885 exceeded the income by £4500, and pledges itself to increased exertion with a view to preventing any deficiency during the current year." He said that the support of London hospitals was not so much a matter of charity or benevolence as it was a matter of duty. He knew that times were hard, for even lawyers felt the pressure; but a great deal of money was wasted that might be turned to better uses. If those who sought to "cut out" their neighbours, to have smarter carriages and higher-stepping horses, or to give more dinner parties, would only think of the little use they were doing in comparison with that attending the support of hospitals they would expend their money differently. Now that there were so many divisions in society, political and religious, all might unite with advantage in the hospital movement; and most assuredly nothing would be found to pay so well as the good that was done to our fellow-men.

Mr. BURDETT, in seconding the resolution, said that if hospitals ever came upon the rates all persons would have to pay for them, and the cost would be infinitely greater than under the voluntary system. The condition of countries without hospitals was simply frightful, as might be seen by the descriptions that had been given of the hideous deformities in China, where a broken limb had to unite as it best could. The development that had taken place in hospitals was well illustrated by the contrast between the state of the Hôtel Dieu in Paris ninety years ago (when some of the beds contained four or five or more patients) and its present highly satisfactory condition. In the fifth district there was about to be constructed one of the best hospitals in London, of which a prominent feature would be the introduction of the provident system, which would entitle it to a proportionately larger grant than that given to hospitals where no such element existed.

The motion was unanimously adopted.

Sir E. HAY CURRIE, in proposing a vote of thanks to the chairman, alluded to the dreadful results that would attend any impairment of hospital efficiency in London. He also paid a tribute to the efforts of the press in promoting the hospital movement, and to Dr. Wakley and to Mr. Burdett for having set the ball rolling.

Mr. WILLETT seconded the motion, which was unanimously adopted, and was briefly acknowledged by the chairman.

THE DUKE OF CAMBRIDGE AND THE MARQUIS OF SALISBURY AT STRATFORD.

ON Saturday afternoon the Hospitals Week was brought to a close by a crowded and enthusiastic meeting held in the Stratford Town-hall. The chair was taken by Mr. E. R. Cook, and there were present Sir E. Currie, Mr. Carr Gomm, Sir T. F. Buxton, Mr. H. C. Burdett, Mr. J. H. Buxton, Colonel FitzGeorge, Captain Storer Smith, Messrs. Custance, Meeson, F. Young, A. Johnston, Ashton Warner, T. Mitchell, A. H. Haggard, and Nixon, Dr. S. Mackenzie, the Bishop of Colchester, the Rev. Canon Scott, the Rev. W. Reaney, and several clergymen and ministers.

The Duke of CAMBRIDGE moved the first resolution, which pledged the meeting to arouse the inhabitants of the district to the importance of maintaining medical charities in efficiency, and urged the clergy and ministers to appeal for increased subscriptions, so that Hospital Sunday might produce not less than £80,000. His Royal Highness said he had the honour of being president of two great hospitals in this part of London, the London Hospital and the German Hospital. In that district they had a deficiency of £15,000, which was their proportion of the deficiency of £40,000 or £50,000 for the whole of London. He observed from the statistics that last year no fewer than a million patients were treated in all the hospitals of London, and that the total cost was £500,000. That gave the singularly small figure of 10s. per patient. If they could not keep the hospitals going a sad calamity would fall upon the community at large. The sum collected last year in connexion with Hospital Sunday was £40,000; it fell £40,000 short of the requirements of the London hospitals. This was why the large figure of £80,000 was presented to them on the resolution. The amount collected was 9s. per patient, and now they wanted to make it 10s. per head. These were marvellous facts. It was hardly known to the public how large an amount was expended, how small was the average expenditure on the individual patients, and how large a number of patients were represented by the additional shilling required. (Hear, hear.)

A leading feature in this question was that they had no State hospitals in this country, and a very good thing too, because he believed all these institutions were far better under private management by individuals who took the trouble which was taken by so many gentlemen on that platform. If they wished to keep the hospitals free from dependence upon State support, which he thought was essential, they must be supported by the people, not only by their sentiments, which he was sure would always go in this direction, but by positive pecuniary contributions. It was a very difficult thing to send a penny or a sixpence to a subscription list, or, it might be, to put it upon the plate on the Sunday, and to feel that they had done the right thing. They might be giving as much as they could individually, and yet feel a sense of shame at giving so little, although they had not the means to give more. It was not the amount—it was the sentiment with which it was given. (Cheers.) Very often a penny or a sixpence represented a far finer sentiment than a £100 note. It was often a more serious thing for a poor man to give a penny than it was for a rich man to give a £100 note. (Hear, hear.) That was why the Sunday collections were of such great value. There could not be two opinions of the value and importance of such a meeting as that, and such meetings all over London would increase the general appreciation of the value of hospitals. Every man and woman could contribute to the great work they had in hand. When there was such a work in hand, there could be no question of convenience or inconvenience. When a man had a great object in view he sacrificed everything to attain it. (Cheers.) No doubt many felt their pockets affected by the depressed state of trade; but sickness, disease, and accident did not stop; they did not go with the times in that respect, and the scarcity of money was no reason why there should be less sickness or fewer accidents. Nay, in times of depression sickness increased because nourishment fell off from the want of employment, and disease resulting from want due to non-employment increased the demands upon the hospitals. (Hear, hear.) There was, therefore, a special claim upon them to give their mite, penny, shilling, or guinea, to these great and useful institutions. If they got the larger sum they required, he should feel more than ever gratified that he had come down among them. (Loud cheers.)

Sir E. HAY CURRIE seconded the resolution, which was supported by the Bishop of Colchester and unanimously agreed to.

The Marquis of SALISBURY moved: "That this meeting regrets to learn that the expenditure of the hospitals and medical charities of this district, in the year 1885, exceeded the income by £15,000, and pledges itself to increased exertion with the view of preventing any like deficiency during the current year." The noble Marquis said—The apology, the defence which we have for this universal movement in favour of the Hospital Sunday Fund is furnished by the peculiar circumstances of the times in which we are speaking. I do not refer only to the great state of depression of trade and industry in London, though that is an argument which has already been alluded to, and is one of the most cogent. It is a reason that applies more especially to this part of London, so thickly populated, so industrious, so full of energy and labour, but one in which the accumulated wealth of the metropolis is not to be found to the same extent as elsewhere. And the consequence is that when depression of trade comes it affects a vast number of purses, it affects all those small subscriptions upon which the support of the hospitals is dependent in this part of London. And men feel that, struggling as they are against the evil and sinister tendency of the times, they may be well excused if they diminish the offerings which they formerly brought forward gladly. It is partly to struggle against this natural feeling that we are here to-day; because as the difficulty of subscribing increases the misery is increasing also. That very want of enterprise, that very depression which affects all, increases the wants of the poor; it spreads the depressing and fatal influence of insufficient nourishment; and the evils of illness or disease which might claim assistance from the hospitals at another time are made worse. It is less easy to cure the spread of the evil over a larger area by the fact of the commercial suffering against which such vast multitudes of our poorer brethren are struggling. That is one of the arguments that should urge you to special exertion at this time. It is one that I hope is transitory. But we must make an effort to get over it without allowing these magnificent institutions to fall into arrear or diminish in utility. And I think there is another argument for a greater effort, which, perhaps, those who summoned this meeting did not foresee at the time. They did not, perhaps, foresee that while we were addressing this meeting a certain ceremony would be taking place which has the effect, besides a great many other effects, of emptying London of a large proportion of its richer population. I mean the dissolution. I do not allude to politics. On this fact rests a great part of the trade of London. It diminishes the number of those from whom subscriptions might be obtained; it makes all charitable effort more difficult than before, and gives Hospital Sunday a worse chance than it otherwise would have had. Therefore, whatever political colour we are of, let us make an effort to diminish this evil effect of political events in which we are all interested. And I confess that when I consider the tremendous interests which we are engaged here to-day to promote; when I consider the comparatively small pecuniary effort that is required in order to stem so much suffering, to remedy so much misery; and when I look outside this room into the turmoil that rages away from our peaceful councils, and think how much energy, how much money, is being spent on other matters, I cannot but have melancholy feeling about it. It has been well said,

> "How small of all that human hearts endure
> That part which laws or kings can cause or cure."

And the contrast between the difficulty of sustaining these admirable institutions, the effort that it requires to collect the small sum that is necessary, with the tremendous energy that is characterising our movements out of doors, makes us feel that there is, perhaps, a little disproportion in our enthusiasm—that we care much for that which is temporary and small, and that we care less for that which is more important than any political interests—viz., the vast amount of human suffering contained in this tremendous population. Perhaps it is that the hospitals suffer because no one disputes their excellence. If they were an interest about whose value there was any controversy they would have their assailants and defenders; and their defenders and assailants would be very keen, and parties would be formed, and there would be leaders and programmes, and, no doubt, great political efforts, and large sums of money collected, and great struggling and political life on both sides. But the hospitals have the misfortune of being so undoubtedly good that nobody will venture to attack them; and therefore the defence of them is comparatively lukewarm and rare. I do not know whether we shall be able to persuade anybody to act the part of what is called elsewhere "the devil's advocate," and give the hospitals a chance of vigorous controversial existence by attacking them thoroughly well; but I am sure it would be very good for them. Not that there would be any defects discovered, for I do not believe there are any; but I believe that it would call attention to them; and in England no duty is thoroughly well performed unless a little fighting is involved in it. But, seriously, I would urge upon you that this claim of the hospitals is prior to any other claim that can be made upon you. It is the only philanthropic kind of charity against which the sternest and most rigid professor of political economy has never ventured to raise his voice. If you relieve the misery that you see in the streets you may be said to be encouraging beggary and pauperisation. You are always exposed to the risk, if you try to relieve suffering, of seeming to discourage the individual effort by which that suffering should have been attacked. But the sufferings which the hospitals relieve are those which no foresight can prevent and no industry or energy can cure entirely for themselves. It is a kind of effort which has no drawback; a kind of charity which leaves no evils behind it; and it is precisely, perhaps, for that reason that it requires more effort to advocate it than is the case with other charities. No doubt these are times of depression. Everybody has less to give than he had before, and we feel that especially when we have to rely on the small contributions which are diminished by distress. But everybody, though giving less, must give something (hear, hear). A certain proportion of his income would be necessary in order to remedy the sufferings of those less fortunate than himself, and let me urge you rather to put other objects of philanthropy behind; rather, if so it must be, to cease from gifts elsewhere, than to allow this splendid machinery for succouring the masses of human

suffering to run any risk of having its utility abridged, or of being thrown upon the dangerous, and insecure, and delusive support of State contributions. These are evils which are worth very serious attention on our part. And, depend upon it, it is an evil from which no one can hope to escape the responsibility by saying that his own position in life is low, and his own means restricted. No doubt the heavier call is upon the rich; but it is equally upon all, and this deficiency will never be filled up unless the vast masses of those whose incomes are not large will each feel the responsibility of contributing what he can to so glorious an object. (Loud cheers.)

The resolution was seconded by the Rev. G. S. REANEY, supported by Mr. C. H. BUXTON, and unanimously agreed to.

Mr. H. C. BURDETT moved, and Mr. F. C. CARR GOMM seconded, a vote of thanks to the Chairman and speakers, and the meeting terminated with hearty cheers for the Duke of Cambridge and the Marquis of Salisbury.

INCIDENTS OF HOSPITAL SUNDAY.

TOO BAD.

A collection was made at the Home Hospital, Fitzroy House, Fitzroy Square, on Hospital Sunday, at the request of the paying patients who were inmates on that day. This collection, amounting to a goodly sum, was taken by one of the nurses, on behalf of the patients, to be given at the offertory at St. Mary Magdalen's, Munster Square, the church which the staff of this hospital attends. No collection was, however, made there on behalf of the hospitals on Hospital Sunday, and the patients' contribution went to swell the amount elsewhere in the evening.

THE RECEPTION OF THE SUPPLEMENT.

The Duke of Cambridge quoted at the Stratford meeting several of the figures published in the First Special Supplement. After the meeting, one of the clergy present inquired if he could be informed where the same information could be obtained for the purpose of his sermon. He was told that it was taken from THE LANCET Special Supplement, and he was asked if he had not received a copy. He replied, "Certainly; but I never looked at it, because I am swamped with communications of a similar character." Contrast this with the following letter from Canon Trench:—"Let me thank you for the Special Supplement of THE LANCET, which must have greatly helped many clergymen, as well as myself, yesterday, by the statements you have so clearly put together."

A VOLUNTARY LAY PREACHER'S CONTRIBUTION.

Mr. John Girling, a voluntary lay preacher and worker amongst the people of Bethnal Green and Shoreditch, obtained the largest amount that he has ever collected, from Hackney Road Mission, Union Street, E., on Hospital Sunday. He truly says, "This year we have done extra well"—a statement which is borne out by the following details, showing how the total is made up:—Morning: Open-air service, at corner of Columbia Road, Hackney Road, 12 to 1.20 p.m. Amount collected, 30s. 4d. Afternoon: School in Mission Hall, Union Crescent. Collected, 10s. 6d. Evening: Service in ditto, 7 p.m. Sum contributed, 24s. Evening: Open-air service at same place as morning, at 8.30 p.m. Collected by 10.30 p.m., 40s. 8d. Total, £5 5s. 6d.

COLLECTING ON A TRICYCLE.

"Cyclist" writes to *The Echo* stating that he spent Sunday afternoon on a tricycle in Seven Dials and Drury Lane amongst the very poor. He everywhere met with a kind reception, but his collection was not nearly so much as in 1885, because certain friendly societies had a church parade and collection before he arrived, in aid of the funds of King's College and the Temperance Hospitals. He adds: "Surely on a day set apart for a general collection, and when appeals were being made in all places of worship for the general fund, it was extremely bad taste on the part of the authorities of these two hospitals to send round the hat on their own account. It may have been only an error of judgment, and can be rectified by their treasurers forwarding the amounts collected to the Mansion House." Some explanation seems to be called for from the authorities of the hospitals in question, and will doubtless be forthcoming.

WHAT AN OFFERTORY BAG CONTAINED.

The *Pall Mall Gazette* gives the following list of the coins given at the collections at St. Margaret's, Westminster, on Hospital Sunday:—

2	Five-pound notes	£10	0 0
2	Cheques (£5 and £2)	7	0 0
1	Postal order	1	0 0
50	Sovereigns	50	0 0
52	Half-sovereigns	26	0 0
117	Half-crowns	14	12 6
168	Florins	16	16 0
578	Shillings	28	18 0
547	Sixpences	13	13 6
281	Threepenny-pieces	3	10 3
732	Pennies	3	1 0
243	Halfpennies	0	10 1½
10	Farthings	0	0 2½
2778		£175	1 7

HOW NURSES CAN HELP!

There are upwards of fifteen thousand skilled nurses in the United Kingdom, many hundreds of whom are engaged in private nursing. The majority were trained at one of the great general hospitals, and most of them in London. One hospital nurse, A. P. Roche, collected from the Earl of Howe's household, on Hospital Sunday, the sum of £9 0s. 2d. She sends the announcement of this collection from Branksome Dene, Bournemouth.

THE EFFECT UPON INDIVIDUAL HOSPITALS.

The secretary of one of the principal Metropolitan general hospitals states that he has been issuing an appeal for funds for some weeks past. During the last fortnight he has received a response many times greater than that he has ever before met with throughout many years' experience. This is no doubt one direct advantage of the new departure on the part of the Hospital Sunday Fund Council.

The following is a list of sums collected, information of which was sent direct to THE LANCET Office.

	£	s.	d.
Christ Church, Trent-park, Enfield	21	15	0
Holy Trinity, Penge	40	0	0
St. Bartholomew's Mission, Camberwell	3	14	6
St. Edmund's, Lombard-street	5	16	4½
St. George's, Tufnell-park	65	2	10
St. John's, Redhill	25	18	8
St. Jude's, East Brixton	78	0	0
St. Luke's, Bermondsey	10	1	10
St. Mary's, Plaistow	4	0	10
St. Peter and St. Paul, Harlington	5	5	0
St. Peter's Mission, Plaistow	1	7	0
St. Stephen's, Coleman-street	10	7	7
St. Stephen's, Canonbury	18	2	5
St. Stephen's, Hounslow	13	15	10

METROPOLITAN HOSPITAL SUNDAY COLLECTIONS, 1886.

THE following statement shows the sums received at the Mansion House on Monday, Tuesday, and Wednesday last. It will be seen that the collections for the years 1885 and 1886 are placed in parallel columns for the purposes of showing the influence exercised by the Hospitals Week. Up to Thursday evening £18,000 had been received, as compared with £14,000 at the corresponding date last year, being an increase of upwards of 25 per cent.

HOSPITALS WEEK WORKERS.

It cannot fail to be a matter of permanent interest, and it would in any case be but justice, to place on record the names of those who have actively exerted themselves in the various districts to make this new departure a success. Of course the honorary secretaries have had much to do and to think of, but all who undertook extra voluntary labour deserve well of the hospitals and medical charities of London. It would be invidious to mention anyone especially, but it is fair to record that the meetings at Lambeth Palace, St. Andrew's Hall, and Stratford were much the most largely attended, although every meeting excited general interest, and all the speakers expressed themselves gratified by their reception and pleased with the genuine interest displayed throughout the Hospitals Week. The institutions and their representatives which took an active part in the work were as follows:

No. 1 DISTRICT.

Rev. A. W. Jephson, Chaplain to the Royal Hospital for Women and Children.
Rev. Canon Erskine Clarke—Battersea and Wandsworth Dispensary.
Colonel Grant—Skin Hospital, Stamford-street.
Mr. W. Owen—General Lying-in Hospital, York-road.
Mr. C. J. Price—South London Medical Aid Institute.
Hon Secretary: Mr. R. Garrard Kestin.

No. 2 DISTRICT.

Mr. Fredk. Cleeve, C.B., Chairman of the Executive Committee, Seamen's Hospital; Mr. P. A. Nairne, Deputy Chairman of the Seamen's Hospital Committee; Mr. George Lidgett.
Mr. Wm. Bristow, Hon. Secretary; Mr. Edgar Sydney; Mr. Thos. Moore, F.R.C.S.; Mr. James Marks.—Miller Hospital.
Mr. T. S. Chapman, Secretary of the Evelina Hospital.
Mr. W. Aste, Hon. Secretary of the Home for Sick Children, Sydenham.
Mr. Jas. Wyeth, Hon. Secretary of the Camberwell Provident Dispensary.
Mr. H. J. Powell, Hon. Secretary of the East Dulwich Dispensary.
Rev. C. Swainson, Chairman of the Blackheath Cottage Hospital.
Hon. Secretaries: Messrs. W. T. Evans and W. J. Purver.
By an oversight the Royal South London Ophthalmic Hospital was not invited to co-operate.

No. 3 DISTRICT.

Mr. Henry Dobbin, Secretary of the Brompton Hospital.
Mr. J. H. Easterbrook, Secretary of the Chelsea Hospital for Women.
Mr. Ernest Morgan, Sec. of National Hosp. for Consumption.
Mr. Fredk. Leach, Hon. Sec. of the Kensington Dispensary.
Mr. W. H. Hughes, Secretary of the Cancer Hospitals.
Captain Blount, R.N., Secretary of the Victoria Hospital for Children.
Mr. J. White Moray, Secretary of the St. Paul and St. Barnabas Dispensary.
Mr. W. C. Meates, Secretary of the Royal Pimlico Dispensary.
Hon. Secretary: Mr. St. Leger Bunnett, St. George's and St. James's Dispensary.

No. 4 DISTRICT.

Mr. Pietro Michelli, Secretary of St. Mary's Hospital.
Mr. Ryan, Secretary of Queen Charlotte's Lying-in Hospital.
Mr. Canning, Secretary of the National Orthopædic Hospital.
Mr. W. H. Prockter, Kilburn Provident Medical Institute.
Mr. Collins, Assistant Secretary of the Lock Hospital.
Mr. G. Thurlow (Hon. Secretary of All Saints' Convalescent Hospital, Eastbourne), Mortimer-street, W.
Hon. Secretary: Mr. A. O'D. Bartholeyns, Secretary of the Middlesex Hospital.

No. 5 DISTRICT.

Mr. Owthwaite—City of London Lying-in Hospital.
Mr. Kershaw—Central London Hospital for Diseases of the Throat and Ear.
Sir E. Saunders, Mr. Gregson, Mr. Ibbetson, Mr. Small, Mr. Willett, Mr. Hepburn—Dental Hospital.
Mr. C. T. Murdock, Mr. Austin, Dr. Potter, Dr. Burnet, Mr. Wm. T. Grant—Great Northern Central Hospital.
Dr. Hopwood, Mr. Callander—London Fever Hospital.
Mr. E. J. Austin—Royal Hospital for Diseases of the Chest.
Mr. Bartram—Islington Dispensary.

No. 6 DISTRICT.

All the hospitals and charities in this district warmly co-operated, but the Acting Committee consisted of
Mr. J. B. Scott—North-Eastern Hospital.
Mr. Ashton Warner—Shadwell Hospital.
Mr. E. Jacob—German Hospital.
Mr. J. Fry—Metropolitan Free Hospital.
Dr. Lazaron—Tottenham Hospital.
Mr. F. C. Carr Gomm, Mr. W. J. Nixon—London Hospital.
Mr. E. Baden—Stoke Newington Dispensary.
Captain Storrar Smith—City of London Chest Hospital.
Colonel Feneran—Poplar Hospital.
Mr. H. N. Custance—Metropolitan Hospital Sunday Fund.
Hon. Secretary: Mr. A. H. Haggard.

Clinical Lecture
ON
ATAXIC PARAPLEGIA.

Delivered at University College Hospital, Feb. 23rd, 1886,

BY W. R. GOWERS, M.D., F.R.C.P.,
ASSISTANT PROFESSOR OF CLINICAL MEDICINE.

(*Concluded from page 3.*)

THESE lesions enable us to understand the origin of the symptoms, at any rate in part. As we have seen, the symptoms are twofold, defect of coördination and defect of power. The lesion is also twofold, in the posterior and in the lateral columns. We must ascribe the incoördination to the disease of the posterior columns. We know that in tabes, ataxy is often the result of their degeneration. If there is a difference between the two maladies in the symptoms produced by the disease of the posterior columns, there is also a difference in the lesion. We must consider these differences in some detail, for we can only understand the origin of the incoördination in ataxic paraplegia by the light of its origin in tabes. What, then, is the mechanism of tabetic ataxy? It is easy to obtain some answer to the question; it is difficult, perhaps impossible, to obtain a complete answer. The chief mechanism is probably the disease of the sensory muscle nerves. The evidence of this is that tabetic ataxy may be due to disease of the peripheral nerves when the spinal cord is unaffected; that it is not due to disease of the cutaneous nerves, and therefore it must be due in such cases to disease of the muscle nerves. It is probable that a very slight affection of these nerves abolishes the knee-jerk, a greater degree causes ataxy, and a still greater degree is required to render the muscles insensitive to pressure and tension. We may sometimes observe a relation between the insensitiveness of the muscles and the degree of incoördination. In a patient, for instance, with much greater ataxy in the right leg than in the left, I found that the muscles of the right leg were insensitive to forcible traction, which caused a keen sensation in the left leg, cutaneous sensibility being equal in the two. There are two ways by which disease of these nerves may disturb coördination. First, it must abolish whatever muscle-reflex action occurs and influences muscular action; and, secondly, it must interrupt the connexion of the muscles with the cerebellum. There is reason to believe that the direct cerebellar tract is the path from the sensory muscle nerves of the lower trunk muscles. It is probable that the fibres of the posterior median column continue the afferent path from other muscles to the cerebellum. Between the grey matter of the post-pyramidal nucleus of the medulla (in which these fibres end) and the cerebellum there is an extensive connexion. The centripetal impulses which traverse these fibres may influence cerebellar coördination, and influence conceptions of posture, without giving rise to sensations comparable to those from the skin. There is, moreover, another possible mechanism. When the posterior columns are extensively sclerosed there must be considerable damage to the short fibres which connect the posterior grey matter at adjacent levels. It is possible that this deranges coördination. I may remind you, in passing, that this is the oldest of all theories of the mechanism of ataxy, being that put forward by the distinguished English physician, Dr. Todd, to whom, if to anyone, belongs the credit of the discovery of tabes. He believed that such association of adjacent parts of the cord was the chief function of the posterior columns, and inferred therefore that in locomotor ataxy the posterior columns would be found diseased, and he subsequently verified his inference by demonstrating the lesion of these columns in two cases. Eight years after the publication of Todd's opinions and facts—viz., in 1885—the theory that the ataxy was due to muscular anæsthesia was put forward by Dr. Russell Reynolds, and one of his statements is worth quoting, on account of the sagacious foresight of the latest conclusions of pathology: "It appears most probable that the centripetal tract of fibres is affected, and that the locality of the lesion is very variable." In ataxic paraplegia there is every reason to believe that the sensory nerves are unaffected in their peripheral parts, and in the lumbar region of the cord the sclerosis is so slight in the root zone that they probably escape there also. But higher up the cord the sclerosis extends through part at least of the posterior median column, and in some cases the direct cerebellar tracts have been diseased. Thus, although the muscle reflex arc is intact, the path from the muscles to the cerebellum must be in some degree interrupted; and there are other facts, which I have not time now to mention, which make it probable that this interruption is more effective in disturbing coördination than is that of the muscle-reflex arc, and therefore that, wherever the disease is situated, whether in the nerves or the cord, it is by the arrest of the impressions that should guide cerebellar coördination that ataxy is chiefly produced. But the locality of the lesion of the centripetal path has one important effect. If it is in the nerves or root fibres, it arrests the muscle-reflex action on which the knee-jerk depends; if it is higher up the cord, it leaves this action unimpaired, and free to become increased under the influence of any other morbid process in the cord which tends to cause such increase. Hence we can understand the persistence of the knee-jerk in spite of the ataxy.

Let us turn now to the second element in the symptoms, the muscular weakness. Loss of power, with increased myotatic irritability, and ultimately tonic spasm, are the characteristics of disease of the pyramidal tracts in the spinal cord. The visible sclerosis in the lateral columns always involves these tracts in some degree, and has been greater on the side of the greatest weakness; hence it seems a sufficient explanation of the symptoms of this second class. There is, however, one difficulty. In some cases in which the paralysis of the legs has been great the disease of the lateral columns has been very slight. Westphal has especially called attention to this discrepancy, and has discussed at some length the question whether the loss of power could be of peripheral origin, rejecting the theory, however, as absolutely inconsistent with the symptoms. I think that the discrepancy is susceptible of explanation, but to make this clear to you I must again diverge, for a moment, to more general considerations.

It will enable us to obtain much clearer conceptions of many facts of disease if we regard the motor path, which extends from the motor cortex of the brain to the muscles, as consisting of two segments, an upper and lower, each of which is similar in its component parts. The upper segment consists first of the motor nerve cell in the cortex of the brain; secondly, of the pyramidal fibre proceeding from that nerve cell, and extending through the internal capsule, the anterior pyramids of the medulla, and the pyramidal tract of the spinal cord; and thirdly, of the termination of the fibre in the grey matter of the cord. The lower segment consists of, first, the motor ganglion cell of the cord; secondly, the motor nerve fibre which extends through the motor nerve root, and the mixed nerve to the muscle; and, thirdly, the terminal ramification of the fibre in the muscle. It will complete the analogy between the two segments if we reflect that the upper segment must terminate, within the grey matter of the cord, in a ramification analogous to that in which the lower segment ends within the muscle. The evidence of such a terminal ramification of the upper segment is twofold. In the first place, the fibres of the anterior roots are more numerous than the fibres of the pyramidal tracts, and hence each of the latter must be connected with more than one of the motor nerve cells. Moreover, the only undivided process of each ganglion cell of the cord is that which constitutes the axis cylinder of a root fibre; the other processes divide and subdivide in the spongy network of the grey substance; and it must be through these and this spongy network that the connexion with the pyramidal fibres is established. This also involves a ramification of the pyramidal fibres. Note next that the symptoms produced by disease of the upper or lower segment of the motor path are very different, but the symptoms are just the same whatever part of each segment is diseased. It is the same when the terminal ramification is diseased as when the cell of origin is destroyed or the fibre divided. We are familiar with this in the case of the lower segment, but it must be equally true of the upper segment. Disease of the terminal ramification in the grey matter will cause

all the symptoms of lateral sclerosis. Further, the axis-cylinders of the nerve fibres of each segment are the prolonged processes of the nerve cells from which they spring—that of the upper segment of the pyramidal cell of the cortex, that of the lower segment of the ganglion cell of the cord. The nerve fibres depend for their vitality on the influence of these cells, and perish when separated. It may reasonably be assumed that the nutritional stability of the fibre diminishes the greater the distance from the cell on which it depends, and that it is lowest in the terminal ramification of each segment. In the lower segment multiple degenerative neuritis is most intense at the periphery, and the degenerated nerve fibres become fewer as we examine the nerves higher up. If there were a corresponding disease of the upper segment, the most extensive degeneration—that of the terminal ramification—would probably escape detection, because it cannot be identified among the numerous structures of the spongy substance; but the disease of the fibres would be traceable in the lateral columns, and would be less than that of the termination, and would lessen as we ascend the cord. So far as the lateral columns are concerned, this is the condition found in many cases of ataxic paraplegia. Hence it is a reasonable assumption that, when the visible degeneration in the pyramidal tracts is insufficient to explain the paralysis, and when it increases as we pass down the cord, there is a greater amount of disease in the terminal ramification of these fibres in the grey matter. We have seen that the sclerosis is often not limited to the lateral tracts. Whether this extension is because it is in part a random process, or whether it is because there is a compound system degeneration i.e., a degeneration of more than one system of fibres, we are at present unable to say.

Thus, gentlemen, the pathological facts, if meagre, enable us to understand the origin of the symptoms in their positive and negative characters, the ataxy and weakness, the preservation of the knee-jerk and its excess with clonus, the absence of anæsthesia, and the slightness of the pains. It is the remarkable clinical uniformity of the symptoms that is the justification for the distinction of the disease. This justification is not annulled by the fact that cases now and then occur which are intermediate between this and other well-defined diseases. We classify by types, but Nature often reminds us that she does not separate where we distinguish. In true tabes there is sometimes loss of power from the addition of disease of the lateral columns to that of the posterior. But these cases, for the most part, emphasise the distinction of this disease from tabes, for the knee-jerk, once lost, never returns because the lateral columns are sclerosed, and it is remarkable with what constancy the knee-jerk persists to the last in ataxic paraplegia. If there is no tendency at the outset to the interruption of the reflex arc, there is none at a later period.

The diseases from which ataxic paraplegia has to be distinguished differ according to the stage of the disease at which the diagnostic problem presents itself. The dominant symptom in the early period is the incoördination; in the later period, the spastic palsy. Hence the disease in the early stage is liable to be confounded with true locomotor ataxy. In discussing the relation of the two diseases we have already considered their differences. Of these the most important is the condition of the knee-jerk, which is lost in the one, excessive in the other. In the rare cases of early tabes in which it is not lost, it is never increased. The presence of a clonus is also exclusive of pure tabes; and so also is the extensor spasm, of which we may often observe some indications while power is still only slightly impaired. Other differences may confirm the diagnosis, but are never necessary to make it, and are indeed not uniform enough to be alone conclusive. In the state of sensation on the limbs, in the occurrence of or freedom from pains, and in the action of the iris, the two diseases present a contrast in the vast majority of cases, although not invariably. From primary spastic paraplegia the diagnosis depends on the presence of incoördination, or in a history of it if voluntary power has become too slight to be susceptible of derangement. Ataxic paraplegia is spastic paraplegia, *plus* incoördination. If the ataxy is considerable, as it often is, the distinction is easy enough, for experience shows that it is chiefly with tabes that such cases are confounded. The so-called "hereditary ataxy" presents a close resemblance to ataxic paraplegia, and is, indeed, intermediate between this disease and true tabes. It is distinguished by its occurrence in several members of the same family, by the common loss of the knee-jerk, and by the presence of nystagmus and of some impairment of articulation.

The greatest diagnostic difficulty is presented by cases which have subacute onset, and the distinction from a local myelitis involving posterior and lateral columns may be very difficult. It depends chiefly on the progressive tendency of the symptoms, which contrast with the regressive tendency of myelitis. It is possible that when there is a degenerative tendency, a focal myelitis may set up a progressive degeneration in the columns concerned, as it certainly may set up a degeneration limited to the posterior columns. A tumour in the middle lobe of the cerebellum may cause unsteadiness closely resembling that of some cases of ataxic paraplegia, and it may also cause weakness of the legs with increased knee-jerk, from the pressure on the pyramidal fibres as they pass through the pons. In such cases, indeed, we probably have the two elements of the disease, although produced in a different manner by lesions in a different position. We have a degeneration of the lateral columns which is secondary instead of primary, and we have disease of the coördinating centre instead of interruption of the path to it. But the weakness in the legs is never great in cerebellar tumour, and other special symptoms are never absent. Occipital headache, vomiting, and optic neuritis are present in most cases, and all are never absent; while in a case in which the pons is compressed, some cranial nerves are usually also damaged.

So far as the prospect of recovery is concerned, the prognosis in ataxic paraplegia is unfavourable. In a few cases I have seen distinct improvement. Arrest is more frequently obtained, but in the majority of cases the progressive tendency of the disease baffles all attempts to check it. The progress of most cases is, however, very slow—far slower than might be inferred from the history of recorded fatal cases; and the danger to life is small.

The treatment of ataxic paraplegia is, in the main, that common to all chronic diseases of the spinal cord. The first important measure is to exclude, as far as possible, from the patient's life all those influences that are capable of producing the disease or of contributing to its production, and which therefore will tend to augment it, whether, in the individual case, they were or were not its cause. The most important of these are four: exposure to cold, exhausting fatigue, falls, and excess, alcoholic or sexual. Walking may be permitted, but it should stop short of fatigue, or at least of more fatigue than a brief rest will remove. If the disease is increasing rapidly, or is recent, and indeed in any progressive case, absolute rest for a week or two may be tried. If it seems beneficial it may be continued for a longer time, or, what is preferable, it may be repeated in a few weeks. If a patient is kept at rest continuously for many weeks, his muscles may become weaker from the mere disuse, and then he may be long in regaining his former level of strength. Drugs are less frequently useful in this disease than in pure tabes, in which their influence is often striking. I am now speaking of the so-called "nervine" remedies, not of anti-syphilitic drugs, which, as a rule, fail to exert any influence over the nerve degenerations that follow syphilis, save in rare instances, chiefly of rapid course and succeeding the venereal disease at a comparatively short interval. This is true also of ataxic paraplegia, but, as we have seen, there is not often any history of syphilis to suggest such treatment. Very small doses of mercury, however, stand on a different footing from large doses and from iodide. They seem to have a tonic influence in the subjects of old syphilis, and during their administration anæmia has been proved to lessen by an observed increase in the number of corpuscles in the blood. Of other drugs, arsenic is that which most frequently seems to do good. Some of my patients who improved under its use took at the same time Calabar bean and belladonna. Quinine may also be given with some apparent advantage. Nux vomica you may give in the early stage, but when spasm is developed both nux vomica and strychnia are better avoided on account of their tendency to increase reflex action and the tonic spasm. The latter, when it becomes great, is a very troublesome symptom, and one over which unfortunately drugs have but little influence. It is distinctly lessened by the process of rubbing the muscles, and after the rubbing is over the spasm remains less for a time, and I have found this process a very distinct help in the treatment of all forms of spastic paraplegia. Upward rubbing seems to have most influence on the spasm. If the patient's constitutional condition permits it, the rubbing may with advantage be combined

with diaphoresis in the Turkish bath. In more than one case the effect of this treatment has been marked, and has distinctly contributed to the very considerable and permanent improvement that was obtained. Electricity is of little value in this disease. Faradaism should be avoided; the irritation of the sensory nerves increases the reflex action and augments the spasm. In several cases I have tried the voltaic current in various ways—applied to the limbs and to the spine, and to both—and in no case have I been able to satisfy myself that any benefit resulted from its use.

One other remark and I have done. Whenever there is retention of urine, or whenever the bladder is imperfectly emptied, the condition must be dealt with by appropriate local treatment. Remember that kidney disease, secondary to cystitis or to mere distension of the bladder, is a common cause of death in all diseases of the spinal cord. In ataxic paraplegia this danger, if not absolutely great, is relatively greater than in many other diseases, because other sources of danger to life, such as bedsores or interference with respiration, are insignificant. There is no doubt that this danger may to a large extent be obviated. I have not in any case, or in any disease, seen an evil result from the early and frequent use of the catheter, and I have known more than one patient die whose life might have been saved had residual urine been regularly removed and the bladder repeatedly washed out. I know patients who are now alive who would, I am sure, have died had this treatment not been adopted. The simple reflex incontinence in which the bladder is perfectly emptied from time to time calls for no interference.

ALBUMINOMETRY BY ESBACH'S TUBES.

By GEORGE JOHNSON, M.D., F.R.S.,
CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL, EMERITUS PROFESSOR OF CLINICAL MEDICINE.

I AM indebted to Mr. Blomfield's paper in THE LANCET of Jan. 23rd, 1886, for a knowlege of Dr. Esbach's method of albuminometry. After reading it I lost no time in obtaining one of the graduated tubes from MM. Brewer Frères, of 43, St. André-des-Arts, Paris; and Mr. E. Cetti, of 36, Brooke-street, Holborn, has made for me a number of tubes with exactly the same graduation. Having made numerous observations on urines containing variable proportions of albumen, I find the results so much more certain and satisfactory than those obtained by any other known method of clinical albuminometry, that I venture to recommend the general adoption of Esbach's method as an easy and accurate means of determining the actual amount of albumen in the urine.

Thinking, from my experience of picric acid as an albumen precipitant, that the addition of citric acid would be found unnecessary, I experimented with solutions of variable proportions of picric acid. First, I tried a saturated solution of picric acid (equal to 5·3 grains per ounce), testing the same albuminous urine with this and with Esbach's solution. The result was that in most instances the saturated solution of picric acid caused a firmer, and therefore less bulky, coagulum, so that the amount of albumen, as read off upon the scale, would appear to be slightly less than that shown with Esbach's reagent. I next tried a solution of picric acid in the same proportion as that contained in Esbach's solution—namely, 1 per cent., or 4·375 grains per ounce. This usually gave a less firm and more bulky coagulum than Esbach's reagent, and would therefore indicate an excess of albumen. Lastly, I experimented on numerous specimens with a solution of picric acid in the proportion of five grains to the ounce—intermediate, that is, between a saturated and a 1 per cent. solution; and the result is that this solution gives results practically identical with those obtained by Esbach's solution of picric with citric acid. The latter solution, on account of its excessive acidity, throws down uric acid more frequently and more copiously than the picric acid solution alone. In two specimens of albuminous urine Esbach's reagent gave so copious a precipitate of uric acid, as if not allowed for, would have led to an excessive estimate of the amount of albumen. The result, therefore, of numerous careful observations is that Esbach's solution of picric with citric acid and a simple five grains to the ounce solution of picric acid give practically identical and equally accurate results; but as the simple picric acid solution is more easily prepared and cheaper than Esbach's compound solution, it will probably be preferred by most practitioners. It is important to bear in mind that if the urine be neutral or alkaline it must be acidulated by acetic acid before the analysis is made.

To test the accuracy of Esbach's method, in one specimen the precipitate formed by Esbach's reagent and the five grains to the ounce picric acid solution having each indicated 1·1 gramme of albumen per litre, the two sediments were separately washed, dried, and weighed by my son, G. Stillingfleet Johnson, in the laboratory of King's College, and the calculated result in both sediments was 1·09 gramme per litre, a difference of only 1-100th of a gramme per litre from Esbach's result. It may be interesting to add that the slightly more dense and less bulky precipitate formed in the same specimen by the *saturated* solution of picric acid was found, when washed and dried, to have exactly the same weight as each of the other two sediments; thus showing that, although the bulk of the precipitate was less, the weight of the dried albumen was the same as that of the other two sediments.

The original account of Esbach's method is published in the *Bulletin Général de Thérapeutique Médicale et Chirurgicale*, tome xcviii., p. 497.

Mr. E. Cetti is now prepared to supply the accurately graduated tubes, with brief printed directions for their use, at little more than half the cost of obtaining them from Paris.

Savile-row, W.

A NOTE ON CYCLIC ALBUMINURIA.

By SIDNEY COUPLAND, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL, AND LECTURER ON PRACTICAL MEDICINE.

THE following case belongs to the interesting class of albuminuria in the apparently healthy, to which Dr. Pavy so prominently drew attention at the Cardiff meeting of the British Medical Association, and again subsequently in the columns of THE LANCET (March 6th, 1886, p. 427). The case resembles those recorded by Dr. Pavy in the fact that albuminuria, to a greater or less extent, occurred once or more often diurnally; but there was less regularity in the period of its recurrence—it was rather "intermittent" than cyclical. The amount of albumen was estimated quantitatively by Esbach's method, of which Dr. Veale has published a full description (*British Medical Journal* 1884, vol. i., p. 898).[1]

Sarah S——, aged sixteen, in domestic service, an active, bright and intelligent brunette, rather undersized, but well-nourished and healthy-looking, not presenting any of the characters of renal disease, was admitted into the Middlesex Hospital on April 1st, 1886, on account of albuminuria. She had been seen a few days previously by Mr. Fardon, the resident medical officer, and at his request had brought a specimen of urine, which he found to be highly albuminous. But after her admission no trace of albumen could be detected, and the same negative result being obtained during the next two days, it was surmised that the previous appearance of albumen in the urine was accidental. On April 5th I handed over the charge of my wards for three weeks to my colleague, Dr. Biss, who, with these facts before him, suggested that the case was possibly one of cyclic albuminuria, and that the urine should be examined at intervals of three hours. This was done for the first time on April 10th, with the result that urine passed at 3 A.M. and 6 A.M. contained no albumen; at 9 A.M. a faint trace appeared, and there was a deposit of lithates; at 12 noon and 3 P.M., no albumen; at 6 P.M., a measurable quantity—viz., 0·3 per cent.; at 9 P.M., 0·06 per cent.; and at 12 midnight, no albumen.

Reverting now to the previous history of the patient, it

[1] The accuracy of this method whereby the number of grammes of albumen per litre of urine can be calculated, was tested by Dr. Veale, and more recently by Dr. P. Guttmann (Berl. Klin. Wochenschrift, 1886, No. 9), the latter further showing that the precipitant used (viz., picric acid one part, citric acid two parts, water ninety-seven parts) is superior to other reagents for the purpose. The method has also been described by Mr. Blomfield (THE LANCET, 1886, vol. i., p. 163) and Dr Cruise (Dublin Journal of Med. Science, June, 1886, p. 489).

does not appear that she had ever had any serious illness, measles in childhood being the only occasion that she could recollect being ill. Two months previous to her being sent to the hospital she began to suffer from some pain in the back and legs and boils in the neck. But she declared herself as feeling quite well, and could not understand why she had been sent to the hospital at all. She was perhaps slightly anæmic, and the temperature on admission was 99·6°, but it fell to normal next day, and never rose above the normal subsequently. Menstruation was regular. She had no headache, slept well, and had a fair appetite. The lungs were healthy, but the cardiac sounds were abnormally loud and booming, the second sound being occasionally reduplicated. There was no evidence of enlargement of the heart. On April 4th she complained of slight pain in the back, with tenderness over the lumbar spine, but this entirely disappeared in two days, and she was allowed to get up.

The discovery of intermittent albuminuria on April 10th led to the repetition of the three-hourly examinations, with the result that at 9 P.M. on the 11th the urine contained 0·06 per cent. of albumen, and at 9 A.M. on the 12th there was a trace of albumen. Menstruation now commencing the observations were suspended for some days, the patient remaining apparently quite well, and assisting in the work of the ward. On April 29th and following days the urine was again, so far as possible, examined every three hours, with the results shown in Table I., the figures denoting the percentage of albumen in the specimens examined. During these days she was on fish diet and milk, but it is noteworthy that on May 3rd, when albumen appeared more abundantly, she was allowed an egg for breakfast. This meal is taken at 5.30 A.M., and although on the three following days the same addition was made to the diet it had no appreciable effect. (See Table II.) The specific gravity of the urine was high, ranging from 1026 to 1036; the urine was always acid, mostly clear, but occasionally depositing lithates. Sugar was never detected, nor blood, pus, or hæmoglobin; and microscopically there were neither casts, nor crystals of oxalates, nor uric acid. The albumen did not yield peptone reactions. The patient was "up" the whole day—i.e., rising at 5 A.M., breakfasting at 5.30, assisting in the ward till 7 A.M., then returning to bed until 11.30 A.M., when she remained up until 8 P.M. She seemed perfectly well, and never complained of fatigue.

During the next three weeks the urine was tested every four hours, so far as possible, but obviously there were occasions when no specimen could be obtained. The observations were made by my house-physician, Mr. T. H. Williams, and the results are given in Table II. One is struck by the variable character of the albuminuria, both as to time of its occurrence and the actual quantity of albumen discharged. Upon six days out of the twenty-three no albumen was found on any occasion of testing; and upon three of these days it must be noted that the patient was kept in bed all day; but that even this absolute rest did not suffice to wholly prevent the appearance of albumen is shown on May 14th, when a small but appreciable quantity was found in the specimen passed at noon. The effect of rest as opposed to activity in controlling the albuminuria—a point clearly brought out in Dr. Pavy's cases—is further shown in the fact that none of the urine passed at 4 A.M. ever contained any albumen, and only on two occasions was albumen present in that which was passed at midnight, four hours after the patient had been

I have already alluded to the apparent influence of rest in preventing the appearance of the albuminuria. Of other possible controlling or exciting agents two only were investigated, and these not to the extent which might have been desired. Thus diet and time of taking food had practically no effect. She was placed on a diet of fish, beef-tea, and milk when admitted, and continued upon this diet until May 14th, when meat was given in place of fish. No effect was produced on the albuminuria by this change. I have already alluded to the somewhat negative result of adding an egg to the diet, but I must admit that more valuable evidence might have been gained had the diet been more

thoroughly changed for stated periods. Again, on four occasions a cold bath given at 8.30 A.M. produced no constant result; once only was albumen present in the urine first passed after the bath, and this in spite of the fact that on another occasion albumen was found in the urine passed just before the bath. So far, then, the case accords with those related by Dr. Pavy, in showing that the only constant factor preceding and accompanying, and probably influencing, the appearance of albuminuria is exercise.

From a study of Table II., it would appear that (excluding the four days on which the patient remained entirely in bed), as regards the time and quantity of albumen passed at different periods of the twenty-four hours, we have the following results: Urine passed at 4 A.M.; eighteen specimens examined, albumen invariably absent. Urine passed at 8 A.M.; nine specimens, albumen present in six, amounting on two occasions only to a trace, and after rest averaging 0·14 per cent. Urine passed at noon; fifteen specimens, in eight of which there was albumen, but on three of these occasions there had been no urine passed at 8 A.M.; on three occasions the quantity amounted to only a trace, and the mean amount excreted on the other occasions was 0·065 per cent. Urine passed at 4 P.M.; only six specimens could be obtained, and one of these was albuminous. Urine passed at 8 P.M.; sixteen specimens, of which no fewer than thirteen contained albumen, which appeared on two days as a trace, the amount on the other days averaging nearly 0·1 per cent. Urine passed at midnight; seventeen specimens, two only containing albumen, and of these the specimen which had a measurable quantity (viz., 0·06 per cent.) was passed on a day when none had been collected at 8 P.M. Lastly, the high range of the specific gravity of these specimens of urine must be noted, this density being in no relation to the albumen, nor to the colour of the urine, which was mostly a pale-straw tint. Except on a few occasions, when there was an excess of lithates, the urine was quite clear and free from deposit. Sugar was not present whenever looked for; but it is right to add that it was not sought for as frequently as albumen was. Looking, then, to the concomitant characters of the urine, as well as the general condition of the patient, one cannot believe that there is any structural disease of the kidney, and can only conclude that the derangement is a functional one, unless one goes further and regards the occurrence of albuminuria in this instance as a purely physiological condition, an idiosyncrasy, which more individuals may possibly possess than we are aware of. It is instructive that, as the urine in hospital patients put up for examination is generally that which is passed in the early morning, the presence of "cyclic albuminuria" might easily be overlooked (as it was indeed in this case at first), since the abnormal characters rarely appear until after the subject has been taking exercise

MYXŒDEMA FOLLOWING UPON REMOVAL OF THE THYROID GLAND.

BY JAMES GORDON, B.A., M.D. EDIN.

THE following case has been under my observation for the past eleven years, and as special interest and importance attach to it in connexion with recent discussions I will give it in detail.

Mrs. A——, aged forty-two, a widow, who had a large goitre of several years' standing, not less than six, was operated upon by Professor Lister eleven years ago, and the entire thyroid gland completely excised. The operation as a piece of surgery was eminently successful, and the patient, so far as this point was concerned, made a good recovery. She accordingly returned home about the end of three months from the time she entered the hospital. When she left she was still weak and pallid, but the weakness and pallor appeared to herself and those concerned the natural result of an operation of such magnitude. Inquiry made subsequently, however, elicited the fact that even before she left the hospital she found her speech was affected, and that on reading aloud for a time she became hoarse. That she was correct in this, and that she had undergone some profound change besides that which the infliction of a great operation would produce, could be detected in her very appearance. Of this no better testimony could be adduced than her first interview w
an aged woman, but possessed of all the
faculties. She was, on the day of her ret
waiting for her daughter's arrival, and wh
stepped in, the mother inquired if "Marion
The daughter replied, "Yes, Marion *has* come,
not recognising her daughter, and fearing she w
sent with bad news about her, exclaimed, "Is
"No," she replied, "I am Marion myself."
mother, not yet recognising her daughter, in
cannot be Marion, for you have neither Mari
Marion's *voice*." This scene shows that already,
date, important alterations were produced in
constitution, and that the origin of this spra
operation. Indeed it was a popular remark, ma
every hand, that she was not recognised.

When first seen by me soon after her return
strangely altered appearance took me by surpris
was pale, yet not the pallor of loss of blood—it w
pasty paleness. It was swollen, especially about th
eyelids above and below presenting a waxy, transpa
The lips were thick, swollen, and of a purple colour,
expression of the face was lost and imbecile-like. T
thought suggested by her look was that kidney affe
was present, but on hearing her speak I was struck
the alteration here. She spoke in an embarrassed ma
slowly, and with a nasal intonation. At this early
then, there were already present the following sympto
feeling of great weakness; feebleness in walking; fa
pale, sallow, pasty, and swollen; speech affected in t
manner just described. The question of renal disease wa
tested. The urine was scanty, no albumen present, and
nothing abnormal in its specific gravity. The heart sounds
were feeble, but nothing otherwise abnormal existed; they
might perhaps resemble the sounds of a dilated heart.
Neither at this time nor at any time afterwards was there
ever anything wrong found with the heart or kidneys; the
latter throughout the course of the case exhibited the
abnormality of a marked deficiency of secretion. Some
days (especially when the bowels were constipated) very little
urine was passed. A pint and a pint and a half were the
common measures of the amount; it never exceeded or
rarely amounted to two pints. There was feebly acid
reaction; specific gravity 1025; phosphatic deposit.

In a short time additional symptoms developed, so that
by the end of six months the patient began to display the
following:—The swelling of the face and the œdematous
condition of the eyelids were more marked; but at this
time, as well as afterwards, this was subject to variation,
being always greater in amount, for example, when the
head was in a dependent position. There was no blush on
the malar eminences, but the point of the nose displayed a
pinkish hue. The fingers, backs of the hands, and wrists
became swollen, coarse, and red-coloured. The fingers
became more awkward and less useful at work; they
fumbled in buttoning her dress, for instance, so that this
operation took a long time, and in cold weather became
almost impossible. She could not pick a small object from
off the floor—she felt no pith in her hands or fingers; for
instance, in washing the floor she found that cloth and hand
rolled round together. Then she noticed that she lost sensation
in her fingers. This was first observed in sewing; she
found she could not feel the needle between her fingers—
could not distinguish between a "darning" and a small fine
needle; so that she was obliged to desist from this industry.
Her feet swelled occasionally—i.e., either with too much
walking or standing, or, on the other hand, when entirely
sedentary. When the feet swelled they felt as if standing
in a wet damp place. But she experienced abnormal
sensations in her feet also at other times—e.g., when lying
in bed. Her walk became feeble and staggering, like one
drunk. She found herself apt to fall, and was always
in fear of doing so. The least object, as the edge of
a carpet, would cause her to tumble. Her limbs felt stiff
and feeble, so that she could not lift them up to mount
a high bed or carriage. Cold weather aggravated the weakness,
as she called it, in her hands and feet. So, too, with
respect to her speech—when exposed to cold she could
hardly utter any word. She always felt cold even in
the hottest weather. Her temperature was always sub-
normal—97°, 97·2°, 97·6°, and sometimes even below 97°;
it scarcely ever reached 98°. When she made an effort to
walk her best, as when she walked on the public road, she
felt her head as if *nodding*. I have not myself observed

but the patient described the condition as re- that of one having the "shaking palsy." This parently arose from weakness of the muscles of the the loss of voluntary power to coördinate their After a time—i.e., when the effort to do it well the phenomenon disappeared. Her tongue was at large; she herself insisted that it was too for her mouth, giving as a proof of this that she to project beyond her teeth in the morning on waking. not, however, say that it presented such extreme bulk never an examination of it was made by me. Her omen became large and bulky universally. This feature marked at the earlier period of the history of the case, l seems to have annoyed the patient most. She felt hamed to appear in public on account of it, lest it should e thought that she was pregnant. This increased bulk did not appear to me to depend so much on any underlying deposit in the abdominal cavity as on relaxation of the intestinal walls yielding to gaseous distension. Her skin became dry and rough, constantly throwing off a coarse furfuraceous desquamation, and even thick scales. Her hair began to fall off, and continued doing so for a period of four years, when at length the scalp became almost entirely bare, and at this stage shed large, coarse, thick scales. The eyebrows also became thin and scanty. The bowels were habitually constipated, never acting without laxative medicine. She feels a lightness and giddiness in stooping or in rising after stooping. On getting out of bed in the morning she had to be careful lest she fell; and similarly, in stooping to light the fire, she was obliged to rest on her knees, otherwise the giddiness would cause her to fall down. Her memory is much impaired, but she is not the least affected as to her intellectual faculties. She is peculiarly placid and self-possessed. Her expression and speech cause her to appear slow and stupid, but she is intelligent enough Her ideation may be slow, but it is quite clear and accurate. Having been previously shortsighted her vision is not consciously affected; there is no impairment of hearing or of sight, and no difficulty ever experienced in swallowing. Her menstrual functions continued unaffected, and was prolonged to the age of fifty. There is one point more to be noted—the patient herself drew attention to it—viz., that the least pressure on the skin left a livid mark behind, so that she was constantly ecchymosed about the hand.

Such was the assemblage of symptoms presented by this case. I say *was* presented (and in my details of the case, the past and the present are mingled together), for there is no doubt that at this moment the patient is so far improved that some of the symptoms have altogether disappeared, while of many others there is amelioration. For example, she has recovered sensation in her fingers, so that she is now able to sew. There is also less anæmia, and decidedly less œdema. Probably an atrophied condition of the subcutaneous tissue exists, but of this I am not sure. The hair has grown again, and, though not luxuriant, is a fair growth. The speech, too, is considerably improved. The amelioration in regard to these points have been, I may say, gradual and insensible. The patient remains but a wreck of what she was, this improved condition notwithstanding.

This case is evidently an example of the cachexia strumipriva of Dr. Kocher, of Berne—a deteriorated state of the system observed by him to follow upon the complete extirpation of the thyroid gland. It is equally manifest that it responds to all the essential clinical features of the disease studied in this country under the name of myxœdema. They are apparently identical pathological conditions. From the standpoint of the surgeon, who sees in the ablation of the thyroid gland the direct cause of the affection, it is justly styled the cachexia strumipriva. From the standpoint of the physician, whose attention was arrested by the swollen condition of the connective tissue from the abnormal development of mucin, the term myxœdema is applicable, inasmuch as this feature is thereby indicated. Dr. Ord, who was the first to make use of the name, was led to believe that this mucoid degeneration was the essential feature in the production of the various symptoms which accompany the disease. The terminal fibrils of the sensory nerves are, he thought, so padded by this mucoid jelly-like tissue that they are cut off from the stimuli of external impressions, and these being slowly received and transmitted to the cerebral centres, the latter are insulated from the natural stimulus of its healthy growth and suffer degeneration proportionally. On the same principle he explains the deficient mental growth in cretinism, and thereby seeks to establish the connexion between cretinism and myxœdema, first suggested by Sir Wm. Gull. This theory as originally set forth seems to have been so far modified, for similar connective tissue changes were also thought to occur in the cerebral centres, whereby deficient mental power results and slow response in the action of the muscles to the will—i.e., the myxœdematous condition occurring in the brain, gives rise to phenomena directly connected with affections of that organ. This hypertrophy of the connective tissue is, upon this theory, looked upon as independent of nervous influence, the nervous disorder being the result of this alteration of that tissue. The remarkable atrophy of the thyroid which obtains in this disease is similarly accounted for by these changes in the connective tissue; the hypertrophy, causing pressure and strangling of the glandular tissue, results in its atrophy. But the condition itself is not considered important in the etiology of the disease, and is on this view secondary, and in no way related as causative in the phenomena of the disease.

Theories based upon pathological lesions are apt to be narrow, and such it would appear to me is the case in regard to the subject now under consideration. That which is here under the guidance of pathological lesion put first ought to be placed last, and that which is last ought to occupy a first place in the sequence of the phenomena of this affection. In the light of the case which I have here reported, it would seem that the connexion of the thyroid gland is at any rate not unimportant, and that it occupies in relation to the various phases of the disease an early and intimate connexion. The gland is wholly removed, and straightway there follows the train of symptoms which have been detailed. There is, on the one hand, an experiment in which the removal of the gland initiates the train of symptoms which, grouped together, give the totality of symptoms which constitute the disease. On the other hand, we have clinical observation in regard to the affection in its idiopathic form, pointing out that there is frequently, if not always, an atrophied condition of the gland present. Therefore both experiment and clinical observation concentrate attention on the thyroid as having somehow an essential connexion with the causation of the pathological state.

That the operation of extirpating the gland may be followed by such consequences there can be no manner of doubt. This woman returned from the hospital completely metamorphosed, so that her identity was questioned. It is alleged that the cause is not in the mere ablation of the gland, but connected rather with certain injuries inflicted by the operation in that region. Accordingly, Baumgarten, of Berlin, suggests that by tying the inferior thyroid close to the gland, the vessels supplying the larynx, trachea, and œsophagus are secure, the recurrent laryngeal is safer, and the cachexia less likely to occur. He further states that in those few cases in which some of the symptoms of the disease were present they entirely disappeared on the performance of tracheotomy. But in Mrs. A——'s case, in whom all the symptoms were typically developed, there never existed at any time any indication for tracheotomy from the involvement of the laryngeal. Others, again, deny altogether the fact of its occurrence. Thus Billroth has never seen, in a large number of cases of total excision, any of the symptoms of cachexia strumipriva described by Kocher. The reply to this is that, inasmuch as it has actually been found to occur in this case and others reported by Kocher, the burden of proving the negative is imposed upon him by observing and reporting on the subsequent state of each case operated upon. I have no doubt that if Sir Joseph Lister were asked as to this very case if he had observed anything of the nature of strumipriva after the operation, he would reply in the negative. Opportunity was not presented to him to ascertain the fact. So also it may be in the case of Billroth. Such was assuredly the case with Kocher himself, for it was only incidentally that the fact was first disclosed to him. On his attention having been drawn to the point, every case of complete excision subsequently examined by him showed signs of the disease except two, and these were found to have, the one a small accessory gland, the other a redevelopment of the goitre.

Special importance may be claimed for the case here reported, since it disposes of the criticism made at the Berlin Conference on Dr. Kocher's report of his cases. It was there alleged that the condition described by him was one which would have occurred, at any rate, independently of the excision of the gland, and that the enlarged thyroid was but a link in the chain of events already in progress—

in fact, a proof of the same,—and that they depended rather on the locality to which the patient belonged (one in which cretinism was prevalent) than on the fact of the extirpation of the goitre. The case of Mrs. A—— is a sufficient reply to that statement, for no such connexion can be instituted in her case. It must further be noted that my patient's case appears to go further and embrace more ground than any of those observed by Dr. Kocher. He thought, for example, that the cachexia was specially incidental to the young and growing, having seen only two above thirty. This woman's age was forty-two. Therefore it is not restricted to the growing age. From this fact, it may be inferred, on the other hand, that the thyroid must have other functions than those which it performs during the period of growth as an elaborator of the blood, with which function it is usually associated. That it has a general influence on nutrition in this way directly is readily accepted; but that its influence should be exerted indirectly through the nerve centres, though not in the meantime capable of being asserted, would appear probable. To limit its relation to nutrition as connected merely with that of the connective tissue is, it would seem to me, too narrow a view. It is not merely a dystrophy of the connective tissue, which is apparent in this cachexia. We find also the nutrition of the integumentary system affected. Indeed, I think that too much stress is laid upon this so-called œdema. Cases are reported in which the myxœdema is not excessive. In this case the condition, though present, was not by any means such as to constitute it the pathognomonic symptom of the disease. The more one became familiar with the case, the more clearly did the neurotic element in it strike the observer. At one time in this woman's case the impressions made on the sensory nerves were so completely lost that she could not sew, not being able to feel the needle between her fingers. Yet at this time there was not present that amount of mucoid padding adduced in explanation of the phenomenon. At the same time, as well as after this condition was recovered from, the nutrition of the integumentary system was markedly impaired. The skin was dry, coarse, and desquamating profusely, and the hair was falling off. The want of sensation gradually disappeared, and the growth of the hair by degrees also was restored, but assuredly the improvement in both these respects was in no way connected with the condition of the œdema. The position, therefore, of those who have surmised that the origin of the disease is central and not peripheral appears to coincide with the various manifestations presented by the case of Mrs. A——.

The connecting link between the thyroid and the assemblage of symptoms under review is at present veiled in obscurity. All that is aimed at by the above case is the contribution of a fact which bears on the gland as the portal through which the solution of the subject is probably to be approached. To show how it is related to the series of phenomena will necessitate that we should possess a fuller knowledge of the physiology of the gland itself. I cannot help thinking, however, that its action is in some way exerted through the sympathetic. Note has been made of the protuberant state of the abdomen and the habitual constipation. The enlarged state of the abdomen always seemed to me to be due in great measure to a relaxed (paralysed) state of the muscular fibres of the bowels, and their consequent yielding to the pressure of flatulence from within—a condition regulated by the sympathetic. The persistent constipation would be accounted for by the same cause. The abnormal temperature, too, points to some relation to the sympathetic. Further, while there was in Mrs. A——'s case a state of unyielding permanent œdema when at its worst, there was also an amount which seemed to vary, such as might arise from the state of the capillaries—a condition likewise which would point to some share in the phenomena on the part of the sympathetic. Does the thyroid gland stand in some direct relation to the great vaso-motor centre of the sympathetic situate in the medulla oblongata? It has always seemed to me that in this cachexia in connexion with the thyroid gland we may possess a parallel to what obtains in Addison's disease, where a profound cachexia is induced in connexion with disease of the supra-renal capsules. It would appear to me of interest to note this, seeing that the mystery of this disease turns upon its relation to those glands which, while they are understood to perform the function of blood glands like the thyroid, are also supposed by many to have some intimate and intricate connexion with the sympathetic system of nerves—if not also of the cerebro-spinal—forming part thereof. As bearing on this point, I may fitly advert to the attention which the special innervation of the thyroid has attracted. In Robin's *Journal de l'Anatomie*, 1875, the great number of nerve filaments with which it is furnished is commented upon. It is there pointed out that these are out of the due proportion requisite of vaso-motors for the supply of the large number of blood-vessels which the gland contains; and it is believed that many of these fibres are sensory. It is stated that small islets of the gland substance are surrounded by plexuses of these nerves, and that the branches passing to and from the gland maintain a telegraphic connexion between these plexuses and the cerebro-spinal axis; while within the gland itself there exists an independent system of telegraphy, the stations being represented by numerous microscopic ganglia, with connecting branches, which do not pass outside the gland. These anatomical minutiæ show that by the structure of the gland it is fitted to exercise special functional relations to the nervous centre; but how they may be utilised in connexion with the question now under discussion awaits solution at the hands of those specially conversant with this department of science. The above are crude suggestions merely.

East Linton, N.B.

FOUR CASES OF

CHRONIC INFLAMMATORY DISEASE OF THE UTERINE APPENDAGES.[1]

BY LAWSON TAIT, F.R.C.S.

MRS. M. F——, aged twenty-eight, a patient in the St. Luke's Home, Edinburgh, under Dr. Halliday Croom, was seen by me on December 18th, 1885, when Dr. Croom and the patient gave me the following history. She was married when about twenty years of age, and within a year had a child with an extremely severe labour, and a long lingering convalescence. She has never been well since that confinement, there having existed marked dyspareunia, which has increased rather than improved. She has had regular and extremely profuse menstruation accompanied with intense pain, that pain being worse for some time before the onset of the period. She has had more or less intense intermenstrual pain excited by movement, and was made much worse by either standing or walking. For years she has been totally incapacitated from performing her domestic duties. In general appearance she was pale and anæmic, with a suffering and anxious expression of countenance; and she had been the round of the hospitals and specialists in Edinburgh, with a uniform failure in obtaining any kind of relief. On examination the uterus was not very large, and it was distinctly retroverted and fixed in its position, and any attempt to replace it gave rise to considerable pain. On each side the general matting could be felt, though no distinct tumour could be made out. The opinion I gave was that the whole contents were matted together, the origin of the condition having been a peremetric attack at the time of the labour; that probably one or other of the tubes was occluded, and that no amount of treatment short of removal of the appendages and the arrest of menstruation would give any satisfactory result. As this conclusion had been previously arrived at by Dr. Halliday Croom, there was no difficulty in making up our minds to it, and therefore on December 19th I operated in the presence of Dr. Halliday Croom, Professors Simpson and Chiene, Dr. Keiller, Dr. Angus Macdonald, Dr. Hart, Dr. Barbour, and Dr. Brewis. I found, as usual in such cases, that the omentum was glued on over the pelvis, and that what operation was done had to be performed through an aperture made to reach the organs. The pelvic viscera was so matted together that it was with difficulty the fundus uteri could be identified, but when this was accomplished it was not difficult to trace the ovaries and tubes first on the one side and then on the other, but a great deal of manipulation was required to detach them. Finally, after a great deal of trouble, they were secured, the pedicles tied by the Staffordshire knot, and the wound, an inch and a half in length, was closed. No drainage-tube was used.

The following letter, dated March 2nd, 1886, was received

[1] Read at the Midland Medical Society, March 3rd, 1886.

from Dr. Halliday Croom giving the further progress of the case: "The patient had no rise of temperature or any bad symptom whatever. She had a perfectly uninterrupted recovery. When I saw her after the operation I was struck by the change in her appearance. Her pinched, suffering look had gone. Her face was round, of good colour, and looked well and cheerful—very different from the appearance she presented when you and I saw her in December last. She still has some pain in her pelvis, especially on exertion; but it is not continuous as it used to be, nor does it interfere with her work, or prevent her enjoying her life, which for seven years past has been a burden. She has not menstruated since the operation, but has some leucorrhœa."

When the appendages were removed and examined by the naked eye, no one, unless greatly experienced in such pathological appearances, could have detected much the matter with them. The tubes were small and atrophied, and the ovaries were apparently normal in size and appearance; the moment, however, they were put in fluid, it became evident, from the masses of flocculent fibres which were attached all over their surfaces, that they had been densely adherent—they were, in fact, adherent over the whole of the superficies. This is only one of the many illustrations in which ignorance of the disease centred in such organs may have, or actually has, led spectators to go away after such an operation with the impression that normal appendages had been removed. From the peculiarities of the operation, no one except the operator can be cognisant of what the real conditions are inside, as none of the adhesions can be seen by the bystanders; and the only evidence to be obtained of these adhesions is the occurrence of hæmorrhage at the time of the operation (frequently very profuse), and the flocculent remains to the adhesions, which can only be seen when the appendages are floated in water, in spirit, or in some other transparent fluid. Fortunately, however, I have in my possession three preparations where the whole of the pelvic contents have been removed at post-mortem examinations, and where the conditions therefore can be demonstrated beyond cavil.

The first preparation was presented by Dr. Littlejohn many years ago to the midwifery museum in the University of Edinburgh, and it is now impossible to obtain any history beyond the fact that the preparation was removed from the body of a prostitute. The conditions are precisely such as I found in the pelvis of the patient upon whom I operated for Dr. Halliday Croom. The Fallopian tubes can be seen to be buried in adhesions, and bands of adhesions pass in all directions, gluing the appendages into abnormal positions, from which they cannot be moved; and to remove these appendages would involve attacking precisely the same extent of adhesion which I had to encounter in the case I have just narrated. In this preparation both the tubes are occluded. (The three preparations were exhibited to the Society.)

The second preparation I also obtained through the kindness of Dr. Littlejohn, and it has precisely the same history, having been removed from the body of a prostitute some months ago; and here again, unfortunately, no history can be obtained. In this preparation the surface of the posterior wall of the uterus was adherent to the rectum, and bands of adhesion passed in every direction, binding the uterus and ovaries together, the ovaries and tubes being considerably below their normal level and fastened there by the adhesions. Both tubes were completely occluded and glued on to the surface of their respective ovaries; these latter were also glued down into the recto-vaginal pouch.

Curiously enough, the third preparation, also taken from the body of a girl who led a loose life, was obtained at a post-mortem made on the very morning on which I was announced to give an address to the Medico-Chirurgical Society of Edinburgh on this very subject; therefore I had the advantage of seeing the preparation perfectly fresh, and of obtaining from the girl's friends, especially her sister-in-law, with whom she resided, an accurate statement of her past history. She had been brought up in a house of ill fame, and at a very early age had fallen into the habits of her associates. She was nominally a worker at a mill, had had an acute attack of syphilitic gonorrhœa before she was fourteen, had gone through a variety of stages of syphilitic infection, and died at the age of twenty from the bursting of a syphilitic aneurysm in the aorta. Her sister-in-law told me that her menstruation was regular and extremely profuse, whilst the suffering which she underwent at each time amounted to agony of the most intense kind, for which she had to take large quantities of spirits to obtain relief. She was totally incapacitated from moving about during the week in which her menstruation occurred, and, without my asking the question, her sister-in-law volunteered the information that the curious part was that the pain was always worse two or three days before the period showed itself. A detailed description of the appendages in this case is as follows:—The uterus was large and heavy, almost as if the girl had had several children, although she never had been pregnant; it was retroverted and quite adherent by dense bands of adhesions (some of which are still visible) to the sacrum; it was opened on its anterior surface. The ovaries, from the presence of adhesions in every direction, were with great difficulty identified, being about three times their normal size. The Fallopian tubes passed curving round them, and were equally adherent and flaccid *in situ*. On the left side the tube was not occluded, whilst that on the right was.

Looking at the preparations now before you, it is impossible to come to any conclusion other than that women, with their ovaries and tubes so matted and adherent together, bound down and incapable of making those movements which it is necessary for the process of impregnation should be made, could be otherwise than absolutely sterile; the machinery of impregnation is wholly out of gear. We have so far, as I regard it, the condition of womanhood existing in three distinct functions. The first is the mere domestic and social life which all women may lead, whether they be wives or mothers. They may be and often are eminently useful members of society, leading absolutely celibate lives. Of this there is of course no doubt at all. There can be as little doubt that in this function, perhaps, they are as useful as in any other. The second function which woman has to fulfil is that of wife; and the third of course is that in which maternity is accomplished. Everyone knows that the condition of wife may be occupied by a woman with perfect happiness, and with a largely extended sphere of usefulness, without the function of maternity ever being even attempted. For the fulfilment of her maternal function and for the perpetuation of the race maternity is a matter of necessity; but it requires nothing save the ordinary every-day experience of the world to prove that the maternal function of woman is limited to a relatively small number. From this we may have abundant indications for our processes of reasoning in dealing with questions of diseases such as those which have been and are to be relegated to one or other of these divisions; few extend into two of them, and only one into the third. The third I have already alluded to. The occurrence of the disease in these women, and the onset of the pelvic inflammation, from whatever causes it may arise, have settled the question of maternity. It is impossible, as I have said, that women so afflicted could ever become mothers. I have attempted to undo such adhesions, and leaving the organs released, in the hope that they might fulfil their functions; but I have absolutely failed; and I believe it is perfectly impossible for any, even the most skilled, surgical efforts to unravel these adhesions and to undo this chronic inflammation to such an extent as to make these organs fulfil their third and most complete function. The pelvic organs are wholly unlike any others. You can rest an inflamed eye by a ball of cotton-wool in a darkened room, and you can suspend absolutely the functions of an inflamed knee-joint by rest in bed and a splint; but you have no means of putting the pelvic organs of a woman at rest short of arresting the function of menstruation. The second function—that of the sexual duties of a wife—may be as completely performed without the uterine appendages, either congenitally absent or absent as the result of surgical interference, as with them. On the other hand, we find from the united evidence of both husband and wife in a large number of these cases of chronic inflammatory disease in the pelvis, that the disease hinders more or less, and in the majority of cases absolutely suspends, the possibility of marital intercourse. The removal of these diseased organs, the restoration of the patient to health, and the freedom from pain that she enjoys after the operation, permit of the gradual resumption of married life, and, after the lapse of a reasonable time, this, the second function of womanhood, may be as completely fulfilled as if she had never suffered.

The first function of womanhood, that of the social and domestic life of a woman, is again absolutely independent of the fact whether she has or has not ovaries and Fallopian

tubes. A woman who has been formed congenitally defective in this matter, may prove as useful a member of society as if she had been completely developed. So it is with those who have submitted to the mutilating efforts of the surgeon, and it must therefore be easily seen that as the disease from which they have suffered must deprive them of that healthy power of locomotion which is essential to complete usefulness in life, so the relief from their suffering by the removal of the diseased organs must restore them to the complete fulfilment of this their prime function in life. The arguments, therefore, which have been, and are still, often adduced against this operation as mutilating and unsexing women exist only in the impure imaginations of those who use them; they have no foundation in fact. If the function of maternity has been by the disease completely abrogated, the operation will make no difference; but if the suffering that these women have to undergo by their diseased condition interferes with their marital and social duties, their restoration to health by operative interference can be regarded only as a blessing to themselves and as increasing their usefulness to those with whom they are associated.

NOTES AND REMARKS ON A CASE OF

CYSTICERCI OF TÆNIA SOLIUM IN CEREBRUM AND FOURTH VENTRICLE OF TWELVE YEARS' DURATION,

PRODUCING INTRA-VENTRICULAR DROPSY, INSANITY, EPILEPSY, AND DEATH.

By J. HARRINGTON DOUTY,

DEPUTY MEDICAL SUPERINTENDENT, WORCESTER COUNTY ASYLUM.

THE following case seems worthy of publication and brief remark, as possessing several points of clinical and pathological interest.

H. B——, a woman aged thirty-one, was admitted into the Worcester Asylum in November, 1877. She had been married rather more than three years previously, and is described by her husband as being, when he married her, in excellent health, perfectly sane, and of an affectionate and cheerful disposition. There was no heredity or other cause of insanity. About a year after marriage she was noticed to become at times dull and forgetful, and began to halt in the articulation of her words, which were sometimes forgotten, wrongly used, or transposed in a sentence. She became less affectionate to her husband, and was now liable to periods of unwonted sulkiness, obstinacy, and quick temper. This state of things went on and developed into a general mental hebetude, which persisted until a few days before her admission, when an attack of acute mania supervened, for which she was brought for treatment.

The notes on admission describe her as being the subject of acute mania, and suggest the probability of her proving to be in the early stage of general paralysis, of which she had some symptoms, such as incoördination of the articulatory muscles. The maniacal state yielded gradually to one of dementia. Six months after admission it is noted that she "walked badly and was unsteady on her legs," and "could hardly speak intelligibly." Three months later, after a convulsive attack, the right limbs became *gradually* palsied, and she was confined to bed; this hemiplegia persisted, and contractions occurred. Two years later she is noted to have been "very paralysed and helpless, simple and idiotic." At this time she could say simple words, such as her own name, or "Yes" and "All right," and could reproduce words she heard spoken. She could also answer a few questions of a simple and common nature, such as "What is your name?" When asked this she always answered by giving her maiden name; this, being the longer known and more frequently uttered name, required less voluntary effort than the less-used married one. Five years after admission (October, 1882) she is described as "much the same." She now talked and chattered like a parrot; could seldom say what she wanted to say, and could not write it; her facial expression, however, of sorrow, surprise, or pleasure was evidence of the absence of sensory aphasia. Six months later it is noted that she had "occasional attacks of vomiting without obvious cause"; this recurred every few weeks, and was evidently of cerebral origin. Examination of her discs was attempted, but found to be impossible, although both pupils were always widely dilated. About this time (May, 1883) she began to have, at intervals varying from a few days to a few weeks, epileptic seizures of an interesting nature. Many of them consisted merely of a scream, followed by a brief period of unconsciousness and marked "epileptic pallor." The loss of consciousness was sometimes only momentary, sometimes of a minute's duration. At times the fits had a convulsive stage, the spasms being general and of the ordinary tonic and clonic type. The right limbs, being palsied and contracted, were not moved during these convulsions; and later on, when the other leg and then the arm became gradually paralysed, the spasms were only noticeable in the left side of the face and the left eye. Sometimes vaso-motor spasm was the only evidence of a fit. These epileptic and convulsive seizures continued with increasing frequency and force, vomiting became more troublesome, the dementia gradually more profound, and aphasia complete, until on March 19th of this year death occurred after twenty-four hours of coma, "Cheyne-Stokes" respiration, and occasional convulsions. The case had been looked upon as one of cerebral tumour.

Necropsy.—The following is an abstract from the notes:—Skull-cap thick. A large quantity of clear fluid poured out on proceeding to remove the brain, and the left hemisphere then fell in like an empty bag; the vertex of the right hemisphere also fell in to a slighter extent. Convolutions, especially the left, markedly flattened; ventricles enormously dilated, containing about a pint of fluid. The left ventricle almost entirely replaced the left hemisphere, whose white matter had disappeared excepting that sublying the anterior parts of the frontal lobe. The white matter of the right side persisted, but was of much less than the normal depth. In the white matter sublying the middle of the left superior frontal convolution was a cyst of the size of a marble, having a membranous wall, and containing clear fluid of gummy consistence and a small white opaque object about the size of half a pea adhering to its inner surface. The cyst was easily lifted from its bed in the white matter, which for about one-eighth of an inch around the cyst was greyish and translucent. The cortex of the left hemisphere was, excepting in the frontal regions, atrophied and buff-coloured, and, with the membranes, formed the walls of the bag-like ventricle. The left corpus striatum and optic thalamus were smaller than the right. The lining of the right ventricle was "frosted," especially over the corpus. On opening the fourth ventricle, a cyst was found lying in its cavity, exactly similar to the one above described both in size and appearance, adhering slightly around the opening of the Sylvian aqueduct. It was easily removed. The aqueduct was dilated to the size of a small quill, especially at its upper end. The other organs presented nothing abnormal in their appearance, excepting a recent congestion of the lungs and kidneys.

Remarks.

1. *The cysts.*—These are pronounced by Mr. J. Bland Sutton to be cysticerci of tænia solium. The absence of heredity or any other predisposing or exciting cause of insanity in the case leads naturally to the conclusion that these cysts were causative of the symptoms, both general and mental. They must therefore have existed *in situ* for twelve years. It is interesting to note that they had not undergone calcareous or other degeneration in that long period of time.

2. *Their position and effects.*—One lay in the white matter which persisted in the left frontal lobe; its site, therefore, was not an uncommon one for cystic growths, and its proper share in the production of symptoms was probably slight. The other lay in an important position: it effectually blocked the fourth ventricle, and thus produced the dilatation of the aqueduct and of the ventricles; as a result "compression" ensued, leading to dementia and general palsy. A few cases with growths in this position are on record by Jacobson and others; one of villous growth in this site, reported by me in *Brain*, October, 1885, had very similar symptoms and conditions.

3. *The epilepsy.*—It is possible that the intra-ventricular dropsy may have caused the epileptic and convulsive attacks; more probably, however, these phenomena owed their origin to the direct irritation of the medullary centres by the cyst in the fourth ventricle.

4. *The insanity.*—The initial mania seems to have been the result of the irritation consequent on the lodgment and development of the cysts. The subsequent gradual abolition of the intellect, ending ultimately in complete amentia, was

but the natural accompaniment of the progressive cerebral lesions.

5. *The aphasia.*—This was normal in the order of its development. It will have been noticed above that the white matter sublying the left special speech centres had been completely destroyed. During the last few years of life voluntary intelligent speech was absent; involuntary and automatic utterances, however, continued until a few days before death—long, that is, after the left speech centres, and in fact almost the whole of the left hemisphere, had ceased to exist. The loss of the left speech centre therefore produced verbal amnesia, and almost effected the total loss of the motor speech processes; these last, however, were taken on to a certain extent by the right hemisphere, whose cortex also achieved (as Hughlings-Jackson says it always does equally with the left) the few simple automatic and imitative (reflex) utterances forthcoming until the onset of the præmortal coma.

6. *The excess of atrophy of the left over that of the right hemisphere.*—This cannot easily be explained. Both ventricles, as already stated, were much dilated; on the right side, however, white matter persisted, though thinned, and seemed to have been capable of conduction to a certain extent until the final stage set in.

7. *The unsteadiness in gait* noticed early in the case doubtless resulted from the pressure of the cyst in the fourth ventricle upon the middle lobe of the cerebellum. Vertigo and reeling gait were also prominent symptoms in the above mentioned case of villous tumour in this site.

8. *Dilatation of the pupils* was also a condition common to both these cases.

Powick.

SIMULTANEOUS LIGATURE OF RIGHT CAROTID AND SUBCLAVIAN ARTERIES FOR ANEURYSM OF ASCENDING PORTION OF ARCH OF AORTA.

REPORTED BY J. A. KELLY, L.M.S.,
RESIDENT MEDICAL OFFICER, HYDERABAD.

THE following case came under the care of Surgeon-Major E. Lawrie, M.B., M.R.C.S., Residency Surgeon, Hyderabad, Deccan, with whose permission I send it for publication.

W. de P——, a Eurasian, aged thirty-eight, had been under treatment since the early part of 1884 for repeated attacks of angina pectoris. He was also troubled by a hoarse cough, accompanied by frothy expectoration. The only treatment that afforded him any relief was hypodermic injections of morphia. In March, 1885, an aneurysm was detected by Brigade-Surgeon T. Beaumont in the ascending portion of the aortic arch; and in August pulsation appeared on the right side of the upper part of the sternum. After a time three ribs were eroded, and a pulsating tumour as large as a tennis-ball showed itself under the skin. There was difficulty in swallowing solid food, which was rejected as soon as it passed the pharynx; and the patient was obliged to live on liquids, which he had to swallow carefully and slowly for fear of being choked. The right side of the neck and face was œdematous and livid; the voice was changed to a whisper; there were paroxysms of angina with urgent dyspnœa, and a very troublesome cough. The pain had greatly increased, and, by preventing sleep, was impairing the patient's general health. No benefit was derived from absolute rest, Tufnell's diet, and large doses of iodide of potassium, and it was therefore decided to tie the common carotid and subclavian arteries.

On Oct. 22nd, a hypodermic injection of morphia having been previously administered, the common carotid and subclavian arteries of the right side were ligatured, under the spray, with carbolised catgut. Chloroform was administered for the first incisions. Afterwards, anæsthesia was kept up principally by the local application of a 10 per cent. solution of cocaine. The edges of the wounds were brought together by horsehair sutures, and thickly dusted with iodoform, and dressings of cloth prepared in a 1 per cent. solution of perchloride of mercury in blood-serum, and dried, were applied. He was ordered fifteen minims of antimonial wine in an ounce of water every two hours. In the evening the pulse and temperature (which before the operation were 90 and 98° respectively) rose to 120 and 101·4°, but subsided the next day, and the wounds healed without inflammation by the first intention. Most of the urgent symptoms connected with the tumour abated within the first week after the operation, and the patient's general condition gradually improved, so that he was able to leave the hospital on Dec. 18th. The radial pulse returned to the right wrist eleven days after the operation.

The aneurysm now (February, 1886) appears stationary, but still pulsates; pain has greatly decreased; swallowing is easily performed; and, with the exception of a dry cough, there are no pressure symptoms.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

UNIVERSITY COLLEGE HOSPITAL.

SECONDARY EPITHELIOMA SURROUNDING LEFT HALF OF THE BODY OF THE LOWER JAW; REMOVAL OF THE GROWTH, TOGETHER WITH HALF THE JAW; RECOVERY; REMARKS.

(Under the care of Mr. CHRISTOPHER HEATH.)

EPITHELIOMATOUS GROWTH secondary to that of the lip, seldom permits of successful removal when it has attained the size of the tumour in the present case. It is unusual to find so extensive an involvement of the bone, as in this instance, with such slight glandular affection, the secondary growths generally appearing in the glands under the jaw and involving the bone later and to a much less extent. The illustration shows well the size and appearance of the growth. Not only was the patient successfully relieved of a painful disease by the operation, but, from the careful manner in which all trace was removed, he has a prospect of prolonged life. For the notes of the case we are indebted to Mr. Bilton Pollard, surgical registrar.

J. H——, aged fifty-five, a labourer, was admitted into University College Hospital on March 22nd, 1886. Two years and a half ago an ulcerated swelling formed in the lower lip, close to the left angle of the mouth. About six months later the growth was removed, and the patient remained well till a year ago, when he noticed a swelling beneath the left angle of the lower jaw. The secondary growth had steadily increased in size up to the time of admission, when the lower part of the left side of the patient's face was much enlarged (see figure). The swelling extended from the middle line beneath the chin to the angle of the jaw, involving all the tissues in the left submaxillary space, and almost surrounding the body of the jaw.

On March 24th, the patient being under the influence of ether administered through the nose, Mr. Heath entered the scalpel about half an inch below the left angle of the mouth, and carried it downwards and outwards over the growth in an elliptical manner for three inches and a half. A similar incision was made between the same points, but at a distance of an inch and three-quarters about the middle. The healthy skin was then dissected up till the limits of the growth were reached; the knife was then sunk down to the jaw in the middle line and through the masseter muscle to the ramus of the jaw, and the bone was sawn across at those two points. The bleeding from the inferior dental artery was arrested by touching it with the point of Paquelin's cautery. The tumour was then drawn outwards and the mass freed by dividing the muscles attached to the left side of the body and angle of the jaw. After the bleeding had been arrested the edges of the wound were drawn together by three button sutures and accurately adjusted with fine wire sutures. The outer part of the wound was left open for drainage. The wound was dusted over with iodoform, and a dressing of iodoform wool was applied.

The parts removed consisted of the left half of the body of

the jaw together with the angle and a small portion of the ramus. It was surrounded below and on both surfaces, except close to the symphysis, by a mass of new growth, which involved the fibres of insertion of the masseter and internal pterygoid muscles, the deep fibres of the mylo-hyoid muscle, and the small muscles on the outer surface of the jaw, together with the greater part of the skin included between the incisions. The submaxillary gland was removed entire with the mass, and the anterior portion of it was implicated in the growth. The body of the lower jaw was diseased by extension of the growth into it. The growth consisted of a squamous-celled epithelioma; the tissue between the epithelial masses consisted of delicate fibrous tissue and small round cells.

The patient was fed twice a day by means of a tube passed into the stomach; each meal consisted of two raw eggs, half a pint of strong beef tea, half a pint of milk, and an ounce of brandy. On the fourteenth day after the operation feeding by the tube was discontinued, and the patient fed himself in the ordinary way. The dressing was

changed twice a day. On the twelfth day after the operation all the stitches were removed; the wound had healed by first intention, except at the posterior part, which had been left open for drainage. The patient was discharged on the twenty-second day after the operation; he was perfectly well and free from pain; there was a small sinus at the posterior part of the scar, and through it a little saliva dribbled.

Remarks.—From the above account and from the woodcut it will be seen that the growth was very large, and that its extirpation involved a great loss of skin and the removal of all the tissues in the left submaxillary space. The wound, nevertheless, healed rapidly and well—a result which may be largely attributed to the care which was taken to keep the wound and the mouth thoroughly clean. With this object in view, the patient's food was poured directly into the stomach for fourteen days after the operation, and the wound in the mouth was dusted twice a day with iodoform. The tumour itself presented some points of interest. The patient had had a growth removed from the lower lip two years before, so that it seemed most likely that the tumour under consideration was epitheliomatous, and that it was secondary to that primary growth. The tumour, however, presented the characters of an independent growth in connexion with the body of the lower jaw, for it almost completely surrounded that bone and consisted apparently of a single solid mass. There were no outlying enlarged lymphatic glands, and the growth was situated at a higher level than is usually the case with growths in the lymphatic glands secondary to epithelioma of the lip. That it was an epithelioma was shown by the microscopical examination, and so, considering the healthy state of the scar resulting from the operation on the lip, the tumour must have originated from a secondary deposit in one of the lymphatic glands beneath the jaw, and spread widely from that centre without infecting other lymphatic glands of the jaw. On the external surface of the latter it spread upwards as far as the alveolar border and over the ramus to the level of the lobule of the ear. A large mass of new growth projected into the floor of the mouth opposite the posterior part of the body of the jaw. At the left angle of the mouth there was a scar which reached down to the growth; but the scar itself was free from new growth. Over the most prominent part of the tumour the skin had a purplish colour and was fixed to the growth beneath, by which it was clearly implicated. The tumour formed a single mass, and no outlying glands could be felt.

BATLEY AND DISTRICT COTTAGE HOSPITAL.

CASE OF EXCISION OF THE OS CALCIS, ASTRAGALUS, AND BOTH MALLEOLI, WITH RESULTING USEFUL LIMB.[1]

(Under the care of Dr. ALFRED SWANN.)

L. P——, aged eight years, a little girl, came under care in June, 1882. Her family history reveals that her father had a piece of diseased bone removed from his right femur thirty-five years ago. This he ascribes to an accident. Both parents are living. There seems to be no positive evidence of struma, syphilis, or phthisis in the family. The child's previous history was that fourteen weeks before admission the ankle began to swell, and she suffered from great pain and feverishness. A medical man was in attendance, and poultices were applied until an abscess formed and burst. This gave very little relief; the ankle still remained swollen and the constitutional symptoms continued. There had been no injury to the joint.

On admission, the child was suffering from feverishness and pain (temperature 103·5°) and a very much enlarged right ankle-joint. On the outer side of the heel, below the malleolus, was a discharging sinus. The whole contour of the heel and ankle-joint was enlarged, and the part was very tender and inflamed. On passing a probe into the sinus, it went for three-quarters of an inch directly inwards and impinged on rough and crackling bone. Movement of the ankle caused slight pain, but there was no grating, and the movement was free. As the sinus ran straight into the os calcis, it was concluded that this was a case of disease of the cancellous tissue of that bone, and on June 15th, 1882, the child being under chloroform, Dr. Swann made a crucial incision, including the opening of the sinus, and, dissecting up the flaps, gouged away a large quantity of gritty and some caseous material from the interior of the bone, and inserted a drainage-tube.

The child was decidedly better after the operation, and for some time the pain disappeared, and the constitutional symptoms improved generally. Three weeks after the operation it was found that the sinus still remained open, the foot again began to swell, and there were great pain and feverishness. The disease still seemed localised to the os calcis; it was therefore determined to remove this, as rapid extension of the disease into the rest of the tarsus was apprehended. On July 7th, 1882, the child having been chloroformed, and an Esmarch's bandage having been applied to the limb, a horseshoe incision was made from the cuboid round the back of the heel to a point opposite to it. This flap was dissected up, keeping as close as possible to the bone, and saving as much periosteum as was practicable. The tendo Achillis and skin over it were split by an incision down to the bone, and dissected off laterally. The calcaneo-astragaloid and calcaneo-cuboid joints were then opened, their ligaments cut, and the bone removed. Attention was then turned to the astragalus, and it was found that this contained a plug of caseous material. This was gouged out. Dr. Swann found, however, that the disease extended so far that he could not avoid opening the ankle-joint; in fact, the ankle-joint was already the seat of commencing disease. (The specimens shown to the Society demonstrated the foregoing very plainly). He therefore enucleated the astragalus. This having been done, the scaphoid and cuboid, which appeared free from disease, although their cartilages were reddened, were examined. Both malleoli were then removed, and a thin slice excised from the end of the tibia, care being taken not to interfere

[1] This case was shown before the Leeds and West Riding Medico-Chirurgical Society on Jan. 15th, 1886.

with the epiphysis. The limb was placed on an angular wire and tin-plate splint, and dressed with dry dressing. As soon as the healing process was fairly established the child made wonderful strides towards recovery, and was discharged on Nov. 13th, 1882, with a useful limb, capable of all ordinary movements.

Remarks by Dr. SWANN.—I have kept the child under observation ever since her discharge from hospital, and at the time of my showing her to the Leeds and West Riding Medico-Chirurgical Society she walked with a hardly perceptible limp, and was in perfect health. She is thoroughly well at the present time. The following points are of interest:—1. Erichsen says, where the disease is extended into the malleolar arch, and where the whole of the os calcis is diseased, no alternative remains but amputation, resection not leaving a useful foot. The above case certainly does not tally with this, as the whole of the os calcis was removed together with the astragalus &c., and an almost perfect limb has resulted. 2. The bones removed contained extensive plugs of tuberculous material. The child is now, four years after the operation, in perfect health. Did the operation by removing a focus of tubercle save the patient from becoming tuberculous? I deem this a question of importance with regard to one's action in future cases of strumous bone disease. 3. The first operation on the os calcis was useless, and I now regard it as having been a waste of time, as I believe partial operations on children's bones are rarely successful, and a free and wide exploration is safer in the first instance.

MEDICAL COLLEGE HOSPITAL, CALCUTTA.

IRREDUCIBLE PROLAPSE OF THE RECTUM TREATED BY AMPUTATION; RECOVERY.

(Under the care of Mr. O'CONNELL RAYE.)

A HINDOO male, aged forty-four, was admitted suffering from prolapse of the rectum of several days' duration. The protruded parts were livid and ecchymosed, with here and there isolated patches of sloughing mucous membrane. The mass was about the size of the clenched fist. The patient was in great suffering and much exhausted. He was placed under chloroform, and careful, prolonged efforts were made to reduce the prolapse, but without success. The measures commonly recommended for the relief of irreducible prolapse—such as excision of strips of mucous membrane, scoring with the actual cautery, nitric acid, &c.—seemed scarcely suitable for this patient, as the bowel had been protruded for several days, and was in a very doubtful state of vitality. Mr. Raye therefore resolved to amputate the protrusion level with the encircling skin. He acknowledged that he should almost certainly have to open the recto-vesical pouch, but hoped, nevertheless, to be able to keep the peritoneum free from contamination. The parts were carefully examined lest they should contain a loop of intestine.

For the operation a Wood's hernia needle was used, armed with a stout silk ligature about two yards long. The needle was introduced along the left index finger within the protruded bowel as far as the level of the anal orifice. The point of the needle transfixed the protrusion from within, and emerged on a level with the skin. A loop of the silk was caught, and held while the needle was withdrawn within the lumen of the bowel. The bowel was again transfixed on the same level, with the needle still threaded, so that the point emerged on the external surface of the prolapsed rectum about one inch away from the first puncture. Another loop of the silk was there similarly caught and retained. This procedure was repeated, just as in the ordinary method of ligaturing a nævus in sections, until the entire mass was included. The external loops were then cut and tied, and thus each included portion was separately secured. The next step was to amputate the mass. Expecting to meet the pouch of peritoneum, Mr. Raye began in front by carefully cutting until he came upon this structure. He dissected the pouch from its surroundings in the manner employed with the sac in some of the modern operations for radical cure of hernia. When the pouch was thus secured, it was raised out of the way and the prolapsed rectum amputated just below the transfixing ligatures. There was no hæmorrhage. Two of the ligatures had transfixed the pouch. He divided these two ligatures, and as portions of the cut edges of the bowel were thus liberated, these edges were seized with Spencer Wells's clamp forceps to prevent bleeding. The prolapsed recto-vesical pouch, being now free, was drawn gently downwards a little, and its neck tied with carbolised catgut just above the point where the ligatures had passed through it. The sac was then cut off and its pedicle allowed to slip back within the pelvis, secured by the catgut ligature. Those portions of the cut edges of the bowel which were held in the clamp forceps were again transfixed with ligatures, which, when drawn tight, completely occluded the orifice through which the process of peritoneum had been protruding. The ring of ligatured bowel was pushed within the anal orifice, the ends of the silk ligatures hanging out for facility of removal, a morphia suppository was inserted, and the man put to bed. The operation occupied about three-quarters of an hour.

There was considerable pain for two days. On the third day the bowels were moved naturally. From the first there was no difficulty in micturition. Two ligatures were found loose on the twelfth day. Two more ligatures came away two days later on. By this time the patient felt quite well, had little or no pain on defecation, and had complete control over the action of the bowels, from which it was presumed that some portion of the sphincter remained. The calibre of the bowel was almost normal, a ring being felt where the ligatured portion lay about an inch within the anus. Whether this ring disappeared subsequently by absorption, or whether it contracted to form a stricture, Mr. Raye is unable to say, as the man absconded on the twenty-first day, some of the ligatures being still *in situ*.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Monocular Iritis. — Interstitial Keratitis. — Pulsating Tumour of Orbit. — Double Chronic Glaucoma. — Corneal Changes in Acquired Syphilis. — Nævus involving Eye. — Paralysis of External Recti. — Mr. Hutchinson's Address.

THE last meeting of the session of this Society, which was also the annual general meeting, was held on the 2nd inst., Mr. Jonathan Hutchinson, President, in the chair.

The annual report of the Council, read by Dr. Seymour Sharkey, showed that the state of the Society was one of prosperity. The members number now 198. The library has been considerably developed, a complete set of Transactions of the Pathological Society, of "Brain," of the Ophthalmic Hospital Reports, and of the Archives de Neurologie having been added.

Dr. BRAILEY showed drawings from a case of Monocular Iritis in a child. The iris was discoloured, and projecting from it were several small greyish-white or pinkish-white nodules; it was adherent at three points to the lens. In the corneal substance were several small greyish opacities. He considered that the disease was tubercular, though the aspect of the patient somewhat suggested congenital syphilis.—Mr. HUTCHINSON said the sequel of the case might throw some light on its nature. The presence of enlarged cervical glands was in favour of a diagnosis of tubercle.

Dr. BRAILEY also exhibited a case of Interstitial Keratitis, in which the left cornea had a somewhat peculiar aspect, and the idea was that it was of tubercular origin. The right eye presented changes which were clearly of a syphilitic type. The left eye showed about a dozen small greyish-white fairly defined nodules.

Mr. A. Q. SILCOCK showed a man with a large Pulsating Tumour of the Orbit. The sight of both eyes had been destroyed by a charge of small shot some years ago. Within two or three days after the accident, he heard a hissing noise in his head. A tumour, occupying the inner angle of the left orbit and extending over the bridge of the nose, began to develop about twelve months after; pressure on the left carotid, which was enlarged, arrested the pulsation and bruit in the tumour, which was not growing rapidly in size. Mr. Silcock said he felt disposed to tie the carotid, but added that Mr. Hulke had advised the use of electrolysis.—Mr. ADAMS FROST was reminded of a case of arterio-venous aneurysm shown by himself to the Society in 1882 (Ophthal. Trans., p. 111). It was the case of a child in whom the signs pointed to fracture of the base of the skull,

The pulsating tumour had first appeared in one orbit, and afterwards in the other. He thought Mr. Silcock's case of a similar nature. That the tumour had not appeared till a year after the accident, although the noise in the head had been audible to the patient from the commencement, was in favour of this view; and recorded cases showed that the primary lesion was aneurysmal varix of the cavernous sinus. The long duration of the case, the tendency of such cases to grow slowly, or even to remain *in statu quo* for long periods of time, should be borne in mind in thinking of the treatment. He should not recommend electrolysis even if the growth were entirely intra-orbital, and this would be completely out of the question if the disease were intra-cranial. Occasional exacerbations of pain and pulsation might be relieved by rest and digitalis.—Mr. HUTCHINSON agreed with the views of the previous speaker. He would not be inclined to advise any radical treatment, but would rather deligate the carotid than employ electrolysis or injections. As showing the little inconvenience that such disease might give, he mentioned the case of a woman who had a large cirsoid aneurysm of the scalp, for which twenty years ago he had ligatured the occipital and temporal arteries, without effecting any improvement in her condition. He saw her again the other day when her condition was not materially altered.

Dr. M. J. SYMONS (Adelaide, South Australia) contributed the history of a case of Double Symmetrical Changes in the Cornea of a man aged twenty-nine, who had acquired syphilis eight years earlier. The patient had first noticed that his eyes were weak, and that there was a film upon them seven weeks before he came under treatment. At the latter date there was thinning, bulging, and opacity over limited areas of both corneæ, without any disturbance of the epithelium. The iris was partially adherent in both eyes. The other tissues of the eye appeared to be healthy. Iodide of potassium effected but slight improvement in a fortnight, when the patient left the hospital.—Mr. HUTCHINSON said the corneal changes had occurred in the tertiary period, but he was not certain whether they were really due to the syphilis. He asked members whether they had seen corneal changes in acquired syphilis.—Mr. NETTLESHIP had seen a few cases of keratitis in acquired syphilis. Even now he had a case under his care in a woman.—Mr. MCHARDY recalled some cases in which inherited syphilis could be excluded.—Mr. LANG had seen a case in a married woman, aged thirty-six, with typical interstitial keratitis and suffering from acquired syphilis; there was no evidence of congenital disease. A second case was referred to in a man: the keratitis occurred twelve years after infection.—Dr. A. MONEY asked what was the latest age at which interstitial keratitis of congenital syphilitic origin could occur; he had seen a case in a woman aged thirty-three, in whom the inherited disease was unquestionable.—Mr. J. HUTCHINSON said he had seen several cases as late as thirty-six years of age.—Mr. NETTLESHIP referred to a case between thirty and forty years of age.—Mr. ADAMS FROST mentioned a case in a woman aged thirty-nine.

Dr. BRAILEY described a case of chronic glaucoma affecting both eyes of a man aged sixty. The man died of aortic aneurysm, which had lasted for twelve years; vision had been failing for three years, but was never insufficient for ordinary purposes; tension in both eyes was increased (T + 1). No operation was performed. Microscopical examination after death showed cupping of the disc, and inflammation of the optic nerve, extending, in decreasing degree, through the chiasma to the optic tract. The iris was neither inflamed nor atrophied. The muscular elements of the ciliary body were inflamed. This case appeared to show that the inflammation and atrophy of the iris so commonly found in glaucoma were entirely secondary to the establishment of the tension; the same remark applied to the inflammation and atrophy of the ciliary body.

Mr. SIMEON SNELL (Sheffield) sent a description of the case of a girl aged seventeen in whom a cutaneous nævus extended over the brow of the right side from the orbit for four inches and involved the upper eyelid. Vision in the right eye had always been imperfect, if not absent. The tension of the globe was increased T + 2, and there was some pain, which was relieved by eserine. No reflex was obtainable from the fundus; the posterior part of the vitreous was occupied by a greyish flocculent substance. The pupil was dilated; at the inner and lower ciliary region there was a staphyloma, and the surface was vascular with deep tortuous vessels. In the circum-corneal region above was a purplish area, which extended upwards and backwards and apparently involved the sclerotic. The eye was enucleated.—Dr. BRAILEY examined the eye after removal. The retina was detached; the optic disc hidden by a great thickening of the choroid; the muscular substance of the ciliary body was shrunken; the iris was inflamed and atrophied. The thickening of the choroid was due to the presence of numerous vascular channels.

Mr. W. J. CANT (Lincoln) contributed a paper on a case of Paralysis of the External Recti. It was that of a man aged sixty-three, suffering from diplopia, headache, slight optic neuritis, and slight albuminuria. Under the influence of saline purgatives the recti gained power, and the double vision became less marked.—Dr. SEYMOUR SHARKEY supposed that it meant to be inferred that the paralysis was connected with Bright's disease; the evidence of the presence of this disease was slight; there was simple neuritis, not albuminuric retinitis. He suggested that the case was one of intra-cranial tumour.—Mr. HUTCHINSON suggested that the case was one of ophthalmoplegia externa in an early stage.—Dr. A. MONEY thought that the disappearing paralysis might be due to the diphtheria, which would also account for the slight albuminuria.

The following card cases were shown:—Mr. W. H. Jessop: Drawing of a case of Leukæmic Retinitis (under the care of Dr. Andrew, St. Bart.'s Hospital). Mr. Marcus Gunn: Peculiar Deep Partial Congenital Excavation of the Optic Disc. Mr. W. J. Cant (Lincoln): Drawings of Symmetrical Disease of the Fundus, probably congenital, in a child.

At the conclusion of the general business, Mr. HUTCHINSON delivered a valedictory address. He congratulated the Society on the appointment of Mr. Hulke as in-coming President, than whom no one was better fitted to carry on the traditions of the Society. Reference was next made to the severe and painful illness of Sir William Bowman, whose health Mr. Hutchinson was able to say now showed some signs of improvement. He then briefly reviewed the work of the Society during the three years' tenure of his office of President. He spoke with special approval of the experiment of collecting facts concerning Graves' disease which had marked the last session; the result was of good augury for the success of future undertakings of a similar nature; indeed, the President considered that this was a sphere in which the Society would find a special field for thoroughly valuable work. He gave several illustrations. The Society might play the part of a concentrating lens in bringing to a focus all the facts which it could collect anent any rare or disputed clinical subject. As some of the topics suitable for such work, mention was made of certain questions regarding tobacco-amblyopia. Does this form of amblyopia ever relapse? He opined from his own experience that it did not. Half an hour's debate, after the attention of the members had been directed to the question for a year or so, should be sufficient to settle this question. He also felt that there were grounds for believing that many cases of tobacco-amblyopia got well, even though smoking was not given up. Do neglected cases ever progress to absolute blindness? With regard to amblyopia potatorum, was this due to the spirits imbibed, or, as some thought, to renal disease or to tobacco? Many spirit-drinkers were also large smokers. Allusion was next made to Mr. Nettleship's case of progressive failure of sight in a woman without any other symptoms. What was the meaning of this temporary extinction of a special sense? Was it allied to the temporary blindness of megrim? The assumption that such cases were due to retro-ocular neuritis required careful investigation. The Transactions of the Society should be of encyclopædic dimensions; systematic efforts were needed; a small committee of energetic men should be appointed, with a view to organise the contributions to be made to the Society; contributions should not be left to chance. The discussion that had taken place that evening had shown that Mr. Morton's case of interstitial keratitis was not unique in the history of acquired syphilis; the severity and persistency of this case were most remarkable, for the results seemed to be deplorable; it was very gratifying to know that twenty years afterwards there had been considerable recovery, and this after mercury and iodides had been entirely discontinued. This suggested that our remedies were unable to influence such sequelæ of syphilis; the inherited form of keratitis was not specially benefited by specific treatment. Another suggestion he had to make for increasing the useful work of the Society. Further particulars and the sequel of cases inserted in the Transactions should be sought for and

recorded in a supplement of the volume. The Society should endeavour to increase its value to general medicine by discovering and publishing accounts of those ocular lesions which indicate disease in other parts of the body. Are the atrophic patches in the periphery of the choroid invariably indicative of syphilitic taint?

A vote of thanks to the retiring President, proposed by Mr. Sympson and seconded by Dr. Eales, was carried by acclamation. The Society adjourned at 10.45 P.M.

The following officers and Council were duly elected for the year 1886-87:—President: *John Whitaker Hulke, F.R.S. Vice-Presidents: *Jonathan Hutchinson, F.R.S.; George Johnson, M.D., F.R.S.; *E. Nettleship; Thomas Reid, M.D. (Glasgow); D. Argyll Robertson, M.D. (Edinburgh); T. Sympson (Lincoln). Treasurer: William M. Ord, M.D. Secretaries: Seymour J. Sharkey, M.B.; *Robert Marcus Gunn. Other members of Council: John Abercrombie, M.D.; *W. A. Brailey, M.D.; Sidney Coupland, M.D.; Walter Edmunds; *H. E. Juler; *William Lang; *J. B. Lawford, M.D.; A. Stanford Morton; *P. H. Mules, M.D. (Manchester); Simeon Snell (Sheffield); J. B. Story (Dublin); John Tweedy. Librarian: W. Adams Frost. (The gentlemen whose names are marked with an asterisk (*) were not in the Council, or did not hold the same office during the preceding year.)

ACADEMY OF MEDICINE IN IRELAND.

Rupture of Pelvic Cyst.—Laryngeal Changes subsequent to Laryngo-tracheotomy.—Granular Disease of Kidneys.

AT a meeting of the Pathological Section, held on April 9th, Dr. C. B. BALL communicated a case of Rupture of a Pelvic Cyst. The specimen was removed from the body of an unmarried lady, aged eighty-six years, who died shortly after the performance of a very trifling operation. She stated that at the time of her menopause a tumour formed in her abdomen, which was attended at the time with considerable menorrhagia. A year ago he saw her for the first time for some trifling complaint, and she then directed his attention to this abdominal tumour, which for twenty years had not given her any uneasiness. It was at the middle line, very firm to the touch, and absolutely painless. About six weeks ago she consulted him for piles, from which there had been considerable bleeding, and he operated by clamping two or three small piles. For two days she went on as well as such cases usually did; and then, about forty hours after the operation, she was suddenly seized with sickness of the stomach, and a state of intense restlessness followed. Her abdomen was somewhat distended, but was not tender, and there was no very definite evidence of peritoneal mischief. The restlessness increased, and she died in ten hours after she was attacked with those symptoms, none of which were referable to the operation. He was enabled to make a post-mortem examination. He had been prepared to find a fibro-myoma attached to the uterus. The first part of that diagnosis turned out to be correct. The tumour was a fibro-myoma; but it was attached, not to the uterus, but by a broad pedicle to the neighbourhood of the right ovary. Section of the tumour showed that it corresponded with ordinary uterine myomata, and microscopic examination confirmed that view as to its nature.

Dr. E. H. BENNETT communicated a case of Laryngeal Changes subsequent to Laryngo-tracheotomy. The specimen consisted of the larynx and trachea of a man on whom he performed laryngo-tracheotomy fourteen years ago. During the building of the Spencer Dock, this man, who was then between twenty-five and thirty years of age, was employed at the excavations. He had previously suffered from typhoid fever, from which he had had a tedious recovery; and, pressed by the necessities of life, he undertook work sooner than he should have done. In a fortnight after leaving the Whitworth Hospital, where he had been treated for the fever, he was admitted into Sir Patrick Dun's Hospital suffering from extreme dyspnœa. His distress was so great that no detailed examination was possible; and he (Dr. Bennett) opened the air-passage by an incision through the crico-thyroid membrane and down through the cricoid cartilage. Immediate relief followed, and a tracheal tube was introduced. It was an ordinary double tracheotomy tube, with a loop-shaped orifice cut in it to facilitate respiration through the larynx. Very soon the mucous membrane projected into this opening; and at each change of the tube a sort of shearing of the edges of the membrane took place, accompanied with hæmorrhage and pain. Consequently that tube was abandoned, and another of more suitable size introduced. The injury to the mucous membrane occurred two or three times in consequence of the withdrawals of the former tube. The man left the hospital cured; and during many years afterwards he (Dr. Bennett) constantly saw him. During his convalescence after the operation a laryngeal examination was made, from which it was discovered that the dyspnœa had been caused by suppurative perichondritis of the larynx. All the tissues were swollen and infiltrated; and the laryngoscope showed that on the left-hand side of the vocal cords there was an opening, through which an abscess had penetrated into the larynx. No necrosis of any part of the larynx ensued. The point of interest was, why it was that in such cases as this, in which laryngeal operations were performed on adults for syphilitic ulceration or for any other affection, the tube had to be always worn afterwards. In several cases he had withdrawn the tube, and the result was that the opening contracted and he had to perform a second tracheotomy and introduce a fresh tube. Did the laryngeal changes result from the mode of operation, or from what other cause? Looking at the present specimen, he was inclined to think that the mode of operation had something to do with it. The first tracheotomy he ever performed was a laryngo-tracheotomy with an incision in the crico-thyroid. He maintained that Boret's mode of performing the operation was the easiest and safest, and much to be preferred to the high operation. In this, as in all the cases of old tracheotomy, the thyroid, cricoid, and other cartilages of the larynx were all ossified. The whole region of the cricoid was shrunk to a minimum, and the larynx was shrunk to the condition of a child's larynx.

Dr. M. A. BOYD communicated a case of Granular Disease of the Kidneys. The patient, a lad aged twenty, was received a couple of months ago into the Mater Misericordiæ Hospital. He had had tympanites of the abdomen, sickness and vomiting for some days previously, with brown typhoid tongue, and was sent into a ward as a case of typhoid fever. On seeing him he (Dr. Boyd) found that his temperature was normal, and, on examining the case more closely, he found him to be suffering from congestion of the base of the left lung, with bronchitis, while his face, upper extremities, and whole body were cyanosed. He was very stupid and lethargic; but his friends said that he had had those symptoms for a considerable time. He had also loss of memory and puffiness of the face, and had not been able to do his work, which was that of a grocer's assistant. For twenty-four hours before his admission he had not passed any urine, and it was withdrawn by a catheter. For three or four days afterwards his temperature was either normal or slightly subnormal—between 97·8° and 98·4°. After the first day in hospital his symptoms were those of uræmic coma, and the lethargic appearances seemed to increase. He complained of pain in the occiput and in the right side of the head. The urine, which was drawn off by the catheter, contained albumen. He (Dr. Boyd) concluded that it was a case of disease of the kidneys, with uræmic coma. He died comatose on the fourth day. It proved to be a case of what Dr. Hammond called red granular disease of the kidneys; but there had been no previous affection of the kidneys. Ten years previously he had had scarlatina, but no symptoms of dropsy or of acute nephritis afterwards. He had pains in the knees and ankles, with effusion at the right knee-joint. The diseased kidney was smaller than the natural size, and lighter than it should be. The cortex, although not adhering so closely as to tear the substance of the kidney, adhered pretty closely to it, and could be seen, white and granular-looking, through the capsule. A section of the kidney also disclosed small hæmorrhagic points here and there, and a granular condition of the cortex itself, and the area of the cortex was very much narrowed.

Sanitary and Judicial Aspects of Cremation.—The Climate of Dublin.

At a meeting of the Subsection of State Medicine, held on April 21st, Dr. H. C. TWEEDY read a paper on the Sanitary and Judicial Aspects of Cremation. Having alluded to the condition of graveyards which gave rise to the Southwood Smith Commission in 1849, he proceeded to show that the dangers arising from the present mode of sepulture were to be traced partly to the contamination of air and water by the gases of decomposition

and other putrefactive matters, and partly by the fact that the germs of several forms of zymotic disease not only retain their vitality in graves, but are capable of indefinite propagation under favouring conditions of heat and moisture, and, becoming liberated on the disturbance of graves, give rise to the several diseases of which each is the specific ferment. The process of cremation got rid of all these dangers, anticipating putrescence by the rapid reduction of the body to its elements, and by the total destruction of all organic germs by the high temperature necessary for the process. A description was then given of the Gorini Crematory now in use at Woking, and various objections to cremation were discussed.—The REGISTRAR-GENERAL FOR IRELAND (Dr. Grimshaw) said the question of cremation was one of great and growing importance. Its sanitary aspect admitted of no discussion, and its sentimental aspect scarcely concerned the medical profession; but its medico-legal aspect required careful consideration in the interests of the public, having regard to the risk of cremation being made use of as a readier method than others to get rid of suspicious cases.—Dr. ATTHILL had long been in favour of cremation, and regretted that the good old system of ancient times was not still carried out.—Dr. HENRY KENNEDY said the question of expense was worthy of consideration in connexion with the subject, as the cremation of paupers would be a considerable tax on the country. He did not believe in the great danger to health alleged to arise from interment. There was no evidence that graveyards were a source of sickness, and therefore it might fairly be questioned that the mischief alleged to arise from such contamination was exaggerated.—Dr. JOHN WILLIAM MOORE regarded the argument from sentiment as altogether in favour of cremation. In the Bible there was nothing from beginning to end opposed to cremation. Dr. Henry Kennedy had not given sanitary or preventive medicine sufficient credit, nor could he agree with him as to the comparative innocuousness of the round of nature which he had described.—The PRESIDENT (Dr. Jacob) held with the Registrar-General that the sanitary aspect of the question was not open to dispute. Indeed, any system by which the results of decomposition could be got rid of would be a boon. Dr. Tweedy's paper had satisfied him that the medico-legal difficulties in the way of cremation had been thoroughly met. It was only in one of 20,000 cases that judicial considerations intervened and a suspicion arose to justify exhumation, and therefore, as regards cremation, they had to deal but with that one case in which the law found it necessary to protect the public against foul play.

Dr. J. W. MOORE read a paper on the Climate of Dublin, based on twenty years' observation. The climate of Dublin was, he said, in the fullest sense, an *insular* one, free from extremes of heat and cold, except on very rare occasions, and characterised by a moderate rainfall (about 28 in.) annually, which is distributed, however, over a large number of days (about 195 in each year). Clouded skies, a high degree of humidity, and a prevalence of brisk winds, chiefly from westerly points of the compass, make up the climatology of the Irish capital.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on May 7th, Dr. J. B. Bradbury, President in the chair, the following communications were made:—

Quadruple Mammæ in a Man.—Mr. POLLOCK showed a patient with two accessory nipples situated below the two natural ones.

Specimens of the Naegele and other Deformities of the Pelvis, their diagnosis, and some points in the management of Labour.—Dr. W. S. A. GRIFFITH exhibited a specimen of the Naegele pelvis which he had recently obtained from a patient who died in St. Bartholomew's Hospital, after a labour terminated by craniotomy; also a model of the similar but bilateral deformity of the pelvis described by Robert, belonging to the museum of St. Bartholomew's Hospital. The Naegele pelvis was a rare deformity, there being only three other specimens in London. Some held that the synostosis and the consequent deformities might be acquired by disease of the sacro-iliac joint and pressure effects; others, including Naegele himself, believed that the ill development was congenital. His own view was that the sacro-iliac synostosis and arrest of development were congenital, and that the deformities of obliquity and flattening were part of the original defect, and only to a slight, if any, extent caused by altered pressure. As to treatment, Dr. Griffith stated that, for almost all cases, the simplest and most effective method of delivery after perforation of the head was by the best modern forms of the craniotomy forceps, or, as some preferred to call them, cranioclasts. The crotchet, like the vectis and blunt hook, was practically obsolete. The cephalotribe was a cumbersome instrument, and would not often be required by a man who thoroughly understood the operation of cranioclasm. He insisted on the necessity of an accurate knowledge of the mechanism of labour for a recognition of the abnormalities of mechanism in the early stages of labour, such as occurred in the rickety and generally contracted pelvis, and would save many women from some of the great risks of obstructed labour, and means could be employed with success that would be useless at a later stage.

A Visit to M. Pasteur.—Mr. WHERRY gave a short account of the new treatment for hydrophobia carried out by M. Pasteur in Paris, and briefly described the method of inoculation and the mode of preparation of the attenuated virus.

Two Cases of Serious Symptoms from Foreign Bodies in the Ear.—Dr. Ingle mentioned two instances in children, in which marked cerebral irritation and pyrexia were produced by the presence in the ear of foreign bodies. In the one case a swollen dead lady-bird was extracted by syringing, in the other some wax and a dried pea. He offered in explanation that the symptoms were produced by pressure on the branches of the third division of the fifth nerve and the vagus, which supplied the cutaneous lining of the canal and drum; further, pressure upon the vaso-motor fibres of the sympathetic might lead to the irritation of certain areas; and these changes would be more likely to occur in children from the small size of their ear-passage and from the fact that in both cases the foreign bodies were capable of enlargement from the absorption of moisture. Dr. Ingle was in favour of syringing as the safest and best method of removing foreign bodies from the ear.

Notices of Books.

On the Fœtus in Utero. By ALEXANDER HARVEY, M.D. London: H. K. Lewis. 1886. The object of the publication of this work is stated in the preface to be to bring prominently forward the "inoculation theory," which is little known, is hardly noticed in physiological text-books, and the literature of which is hardly accessible. The book consists of a series of papers published in the *Edinburgh Monthly Journal of Medical Science* in 1849 and succeeding years, as well as elsewhere. The subjects of the essays are on the fœtus in utero (*a*) as inoculating the maternal with the peculiarities of the paternal organism (and on the influence thereby exerted by the male on the constitution and reproductive powers of the female); (*b*) as influenced in its development by mental states in either parent; (*c*) as the channel of transmission of constitutional syphilis from the male to the female parent. The book also includes a statement of Count de Strzelecki's law of relative sterility. The word "inoculation" is used in its proper and literal sense of *grafting*, and the chief facts in the book are those which may be taken to show that a mother may acquire through the fœtus the peculiarities of the father, so as to transmit them to future offspring, and that a woman may live with a syphilitic (secondary syphilitic) husband, and remain uninfected till she becomes infected through the fœtus. We are surprised to hear that these theories are little known; we were under the impression that they were generally known and accepted. It appears that the former of them was first propounded in 1849 by Mr. James Macgillivray of Huntly, a veterinary surgeon in Aberdeenshire, and that the latter was first set forth by Dr. Ramsbotham in a clinical lecture on Abortion in 1835. The author's essays are amplifications of them. The book is interesting as a record of the progress of a

subject. The essays are obviously the work of a highly educated and scholarly person; of their matter, some has long since been incorporated and assimilated, some has gone the way of Count Strzelecki's "law."

Companion to the Latest Edition of the British Pharmacopœia. By PETER SQUIRE. Revised by PETER WYATT SQUIRE and ALFRED HERBERT SQUIRE. Fourteenth Edition. London: J. and A. Churchill. 1886.—Squire's Companion has reached a fourteenth edition, a striking proof of its popularity. The work was originally written by Mr. Peter Squire, and the first edition appeared in 1864. Since his death in 1884 it has been edited by his sons. The present issue has been brought into accord with the last edition of the British Pharmacopœia. It seems almost absurd to speak of it as a "Companion" to the British Pharmacopœia, seeing that it is commonly used as a substitute for that work. It is so thoroughly practical that it is of the greatest use, not only to chemists and those engaged in dispensing, but to physicians and prescribers generally. The amount of information it contains is really astonishing, much of it being quite new and original. The article on Belladonna, for example, is apparently almost entirely rewritten, and contains a great deal that is not only novel but thoroughly practical. On the first page we find an excellent account of the Abrus precatorius, with a selection of formulæ from Shoemaker and others. On the next page there is much that is interesting about emulsions, and so on throughout the whole book. We have noted seventy-two pages which seem to have been entirely rewritten for this edition. The faults and omissions are few and far between, but we may mention that we do not find picrotoxine in the index, and that the note on pure terebene is most incomplete. The account of the therapeutic action of nitro-glycerine is not strictly accurate, and we doubt if the credit of its introduction should be assigned to Dr. Ringer. A good formula is given for the preparation of syrup of wild cherry bark, now so extensively employed as a flavouring agent. The whole edition has been most carefully prepared, and fully maintains the high reputation of the work for care and accuracy.

Anatomie menschlicher Embryonen. Von WILHELM HIS. III. Geschichte der Organe. Mit 156 Abbildungen in Text und Atlas. Leipzig: Verlag von F. C. W. Vogel. 1885.—The contents of the third part of this interesting and valuable work concern the development of the human embryo to the end of the second month, as regards the alimentary canal, the mouth with the various cavities connected with it, the nose, the lower jaw and neighbouring parts, the front wall of the mouth and pharynx (thyroid body, entrance to the larynx and tongue), the cranial nerves and their relation to the segments of the head, the muscles of the head, the salivary glands and teeth, the special development of the appendages to the thyroid body (ductus thyreoglossus, lingual and thyroid ducts), the thymus, the development of the neck, the heart, the arch of the aorta, the modification of the great primitive cardiac veins, the external ear, and the umbilical cord. The method adopted has been that by consecutive sections, a most laborious process, but one which gives certain and trustworthy results. The volume, indeed, represents months and even years of work. The text is illustrated by 156 figures, and the Atlas contains 15 beautiful plates. The writing, as well as the illustrations, bears the stamp of earnest and truthful description, and the whole work forms a contribution to human embryology of the highest scientific as well as practical value.

The Baths, Bathing, and Attractions of Aix-les-Bains, Savoy. By W. WAKEFIELD, M.D. Pp. 223. London: Sampson Low and Co. 1886.—In this Guide to one of the most important health-resorts in France, the author does not profess to go into any detail respecting the class of cases which might be advantageously sent to it for treatment. He has endeavoured rather to "give the members of the medical profession and the public some general information under the various heads, 'what the waters of Aix are good for; their administration; what kind of a place Aix is; how and where found; what the visitor should do when Aix is reached.'" The book is therefore more intended for the public than the profession, though it contains much information which will be found useful to the latter. The advice he gives to the invalids is judicious, and especially his caution against "the well-meant but hurtful advice of those amateur physicians, so plentiful at all thermal centres, who, having undergone a course of treatment themselves, imagine they are perfectly qualified to lecture or advise others as to the proper course to be pursued." The latter half of the book consists of an account of the numerous places of interest in the vicinity of Aix and the means of visiting them. It appears to have been carefully compiled, and will doubtless prove very useful to those health-seekers who are able to take a moderate amount of exercise, and still more to those in health who have accompanied them, and who are apt to weary of the monotony of a residence in a watering-place, however beautiful it may be. They will find abundant variety in the walks and drives sketched out for them.

Carlsbad and its Environs. By JOHN MERRYLEES. With a Medical Treatise on the Use of the Waters, by B. LONDON, M.D. Pp. 199. London: Sampson Low and Co. 1886.—*Guide to Carlsbad.* Edited, under the authority of the Mayor and Town Council of Carlsbad, by W. SCHACHT and Co. Pp. 37. London: Trübner and Co. 1886.—The first of these works is a very readable guide-book for the use of English-speaking visitors to Carlsbad. It appears to contain all the information necessary to enable them to find their way there, to locate themselves comfortably, and to go through the usual course of treatment advantageously if invalids, or to pass the time of their visit pleasantly if in good health. The latest analysis of the principal springs, which are sixteen in number, is given, and may be found useful to the profession when called upon to advise patients as to the selection of a watering-place. The second part—the Medical Treatise—appears to have been written more for the use of the laity than of the profession, and might, we think, have been judiciously curtailed and made much less technical in its language. A good index would have added materially to the value of the book. Schacht's Guide does not give any professional information regarding the properties of the waters, but it contains all that is necessary for persons intending to visit Carlsbad respecting the various routes by which it may be reached, the regulations affecting the letting of apartments, the tariff for carriages and other means of locomotion, and the course to be pursued in the event of any dispute arising with lodging-house keepers, cabmen, &c. It has the advantages of being short, clear, practical, and portable.

Bright's Illustrated Guide to Bournemouth, Christchurch, New Forest, Poole, Wimborne, Corfe Castle, &c. By C. H. O. CURTIS. Pp. 182. Bournemouth: Bright. 1886.—This will be found to be a very useful guide to those who select Bournemouth either for a holiday retreat or as a health resort. The "general description" is rather too much in the florid style which seems peculiar to guide-books, and the detailed account of the various churches is unnecessarily long, occupying nearly thirty pages; but the book gives all the requisite information about Bournemouth itself and its suburbs, and a good account of the numerous places of interest within easy reach of it. A brief chapter on the climate of Bournemouth by Dr. J. Davison, which contains tables of the monthly temperature, humidity, and rainfall, extending over

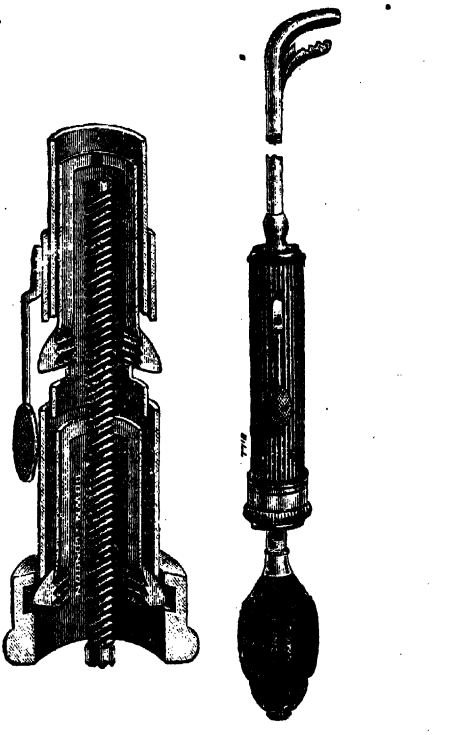
a series of years, may be found useful in considering whether it is likely to prove a suitable health-resort in particular cases.

Ambulance Work: Questions and Answers upon "First Aid to the Injured." By J. W. MARTIN, M.D., and J. MARTIN. Pp. 47. London: Baillière and Co.—This little book has been compiled by the authors, not with a view to supersede, but to supplement, Shepherd's "First Aid to the Injured." The form of question and answer may probably be found an advantageous method of conveying instruction, and the cautions given against the pupil supposing that by having attended a course of ambulance lectures he has become qualified to take the place of the physician or surgeon are judicious. We are afraid, however, that some of the answers, especially in the anatomico-physiological portion, are beyond the general grasp of many of those for whom the book is intended. Nor are we quite satisfied with all the practical portion. For instance: "Q. If a child has swallowed a small coin, a bean, or other small, hard body, what might you do with success?—A. Hold the little patient up by the heels, inverting him." There might be considerable risk attending the carrying out of this process of inversion under such circumstances, unless performed by competent hands.

Dictionary of National Biography. Edited by LESLIE STEPHEN. Vol. VII. London: Smith, Elder, and Co.—The seventh volume of the Dictionary of National Biography, which has just been published, extends from "Brown" to "Burthogge," and its contents, in accuracy and literary polish, fully equal those of the preceding volumes. The favourable opinion which we expressed in our last notice of this publication has not been in any way diminished, and we congratulate Mr. Leslie Stephen on the manner in which he is performing his necessarily responsible task.

John Leech's Pictures of Life and Character from the collection of "Mr. Punch." London: Bradbury, Agnew, and Co.—We have received the first and second parts of this work, which is now being published in monthly instalments. It is well got up, considering the lowness of the price at which it is offered, and when completed will contain nearly 4000 sketches by the great master of English caricature, illustrating every section of social life from 1842 to 1864. John Leech's sketches are so familiar that it is unnecessary to describe them, and to everyone who does not possess a complete and handy copy of them we can advise the purchase of the collection which forms the subject of this notice.

Medical Annual, 1886. London: Kimpton.—The proprietors of this Annual have devoted several pages of the contents to a summary of the recent advances made in medicine and surgery, which will be found useful by members of the profession. The remainder of the volume is occupied with the subjects which formed the contents of the Annual for 1885, and affords a useful source for reference upon many questions of interest to medical men.



PRESENTATIONS.—On the 22nd ult., on the occasion of their annual dinner, the members of the West Kent Medico-Chirurgical Society presented Dr. Prior Purvis, of Blackheath, with a drawing-room clock and two vases bearing the following inscription:—"Presented to Prior Purvis, M.D. Lond., by the members of the West Kent Medico-Chirurgical Society, in recognition of his valuable services as treasurer extending over a period of thirty years." Mr. D. A. Fraser, M.R.C.S., L.S.A., has also been presented with a clock by the inhabitants of Burnham, as a mark of their approval of the manner in which he has discharged the duties of medical officer of health to that town.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.—Founder's Day at this institution was celebrated on the 6th inst., when a large gathering of the friends and old pupils of the College attended to witness the distribution of prizes.

New Inventions.

A NEW LITHOTRITE.

IT has occurred to me, during the operation of lithotrity, that having with much patience seized a fragment of stone, I have again lost it in the attempt to lock the instrument, the morsel being of such size that the threads of the screw would not bite. An inspection of most old lithotrites will show that this must be no uncommon accident, as it will be seen that the edges of the male screw are burred from the force used to make it lock; and although theoretically it would appear impossible to remedy this defect, as a fresh catch would be necessary at every point of the screw, practically such perfection is needless, and the instrument (which has been ably made from my design by Messrs. Down Brothers of St. Thomas's-street) answers sufficiently well. Its novelty consists in two locks, so set that whenever the crests of the female screw of the first impinge directly on the crests of the male screw, the second lock can be brought into play by

moving up the catch with the thumb without altering the position of the operator's hands. By this arrangement the pitch of a screw like this of fourteen threads to the inch is reduced to one of twenty-eight, and the chance of jerking away the stone is proportionately lessened; and although the weight and length of the handle are increased, I consider that no disadvantage, as it affords a firmer hand grasp.

East Rudham. ALAN REEVE MANBY.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—The council of the Society had arranged for a Colonial and International Congress on Inebriety in London during the current month, but the General Election has made postponement desirable. The Congress will meet when Parliament sits.

THE LANCET.

LONDON: SATURDAY, JULY 10, 1886.

THE College election, which is just over, will be held remarkable in times to come, because the Fellows, for the first time, have elected a general practitioner into the Council; and, secondly, because they have elected two provincial in face of some very eligible metropolitan Fellows. As regards Mr. SIBLEY'S election, the Council may be fairly congratulated. Apart from the obvious desirability of the great mass of the profession—the general practitioners—being directly represented, Mr. SIBLEY cannot fail to be a *persona grata* to the Council. His well-known business aptitude and his liberal and tolerant views specially qualify him for his office, and will prove of eminent service in the Council chamber. We rejoice, however, not on these accounts alone, but because in this departure from routine we recognise a wise and advancing liberalism among the Fellows which augurs well for the future of the College. This liberalism is further illustrated in the simultaneous election of two provincial Fellows—a fact which has not previously occurred, as far as our memory serves us. At the present, therefore, the Council contains four members—a still too small, but a juster, proportion of provincial representation than has obtained at any previous period.

It was natural that Mr. LUND should head the list, and we are pleased to congratulate him, and on his majority over the next and following candidates. His votes, moreover, included only one plumper, Mr. SIBLEY having received three. To plump is usually a sign of personal over general considerations, of having zealous friends rather than special merit. It detracts from rather than adds to a candidate's success. Besides, it interferes with that appreciation of the esteem in which other candidates are held, which is as useful to the candidates themselves as it is interesting and serviceable to the voters at large. It may also be argued that Fellows are not competent to vote when they thus shirk the responsibility which a more orthodox division of their votes implies. Mr. BERKELEY HILL, Mr. REGINALD HARRISON, and Mr. WILLETT, with each ten plumpers, are no better or worse off than they would have been without them. On the whole, we must congratulate the Fellows, and the Members of the College also, on the result of the past election. The Council as at present constituted is more largely liberal and progressive than at any previous period; and we may look forward hopefully to the future for the realisation of those reforms which we have so often and so urgently advocated.

Following precedent, Mr. JOHN WOOD would have become President; it is not surprising, however, that Mr. SAVORY has been re-elected in acknowledgment of his valuable services, of the admirable manner in which he has discharged his presidential duties, and also of his position and eminence as a surgeon. We congratulate Mr. SAVORY on being the first President on whom the honour of re-election to the presidential chair has been conferred since the name of the head of the College was changed from that of "Master." The only approach to a parallel case was in 1831, when Mr. ROBERT KEATE was chosen President after having occupied the chair part of the previous year in consequence of the death of his predecessor, Mr. R. C. HEADINGTON, before the completion of his term of office. Mr. WOOD'S turn is merely postponed for a year.

We can only express a hope that the new Council will use their best endeavours to bring about with all celerity an adjustment of the present differences subsisting between them and a large number of leading Fellows, and that they will also find means of enlisting the Members and their goodwill in the development and service of the College by timely and judicious concession in the directions sought by both classes of their constituents.

WE have recently given account of Mr. W. H. POWER'S report upon the prevalence of scarlatina among the consumers of milk from a farm at Hendon, and have expressed the conviction that the evidence which he adduced to show that a cow ailment caused the malady in man must be accepted as sufficient for this purpose. This evidence, it is true, was merely circumstantial, but the marked coincidence in the behaviour of the affections among the cows and among the consumers respectively placed it beyond reasonable doubt that the one was responsible for the other.

We have now before us the report of Dr. KLEIN upon his own share of the investigation which was undertaken by the Medical Department of the Local Government Board, and again we find very strong corroboration of the conclusions at which Mr. POWER had arrived. It was Dr. KLEIN'S duty to consider the subject from a different point of view than that taken by Mr. POWER, and to test by such experiment as was possible the question whether the cow malady was a communicable disease, and whether in its results upon this animal there was indication of its being concerned in the production of scarlatina in man. The subject was not altogether a new one. In the year 1882 scarlet fever had been distributed with milk in the parishes of St. Giles and St. Pancras, and this milk had been received from a country farm where the condition of one of the cows was noted by Mr. POWER, who conducted this inquiry. This cow had recently come into milk, and was evidently not in good health, as was shown by the fact that its hair had been shed in patches. In the absence of other evidence as to how the milk received infection, it was felt desirable that experiments should be made to show how far it was possible to inoculate cows with human scarlatina. It is unnecessary to refer more in detail to the lessons which were then learnt than to state, in the words of Dr. BUCHANAN, that it was found that a definite disease was producible in the cow by means of scarlatina infection, and that most readily when the cow was in milk.

A noticeable condition of the cows of the Hendon farm was the shedding in patches of their hair, resembling in this respect the cow which had attracted Mr. POWER'S attention in the previous investigation; but at Hendon were the further symptoms of vesication and ulceration of the teats and udder, supplying Dr. KLEIN with material for the prosecution of further inquiry. This virus was used for the inoculation of certain calves, with a result which clearly demon-

strated that the affection was transmissible from one animal to another, producing effects which resembled the disease found in the Hendon cows. Further, the virus was cultivated in nutritive gelatine and other suitable materials, producing a micrococcus which grew freely in these substances in a manner resembling that of the streptococcus of foot-and-mouth disease, but differing from this organism, when cultivated in milk, in the fact that the latter does not affect the fluid character of the milk, whereas the former turned it solid. The inoculation of two calves by a third subculture in agar-agar mixture of the streptococcus of the disease among the Hendon cows led to the most instructive results. One animal was found dead twenty-seven days after inoculation. An examination of its body gave evidence of marked morbid changes in the peritoneum and internal organs, the kidneys were large and much congested, the liver greatly congested, and also the organs of the throat. The second calf was killed some nine days later, and very similar appearances were found to exist. There was, moreover, a disease of the skin and in the mouth which was similar to that found in one of the Hendon cows which was the subject of observation and in one other calf which had been inoculated. Writing of the microscopical appearances, Dr. KLEIN notes the close resemblance of the minute anatomical characteristics of the eruption to those of human scarlatina, and particularly the disease in the liver and in the kidney. This latter organ, he states, 'corresponds so closely with the kidney of an acute case of human scarlatina, that sections made of the one and compared with those of the other show no difference whatever."

Dr. KLEIN, moreover, found some reason for believing that the milk within the udder of a cow suffering from this disease did not contain the micro-organism, but that it became infected at the moment of milking from the ulcers on the teats; and he points out that the organism would find in the milk a good medium in which to multiply, and that the milk would then practically correspond to an artificial culture of the streptococcus, such as was found capable of setting up a general disease when inoculated subcutaneously into calves. The feeding of animals with food containing this virus has not yet been attempted, and it is obvious therefore that the experiments are as yet incomplete, and even those which have been performed deserve repetition. But enough has already been learnt to confirm the opinion that Mr. POWER'S labours have brought us face to face with the origin of scarlet fever in man, and that the prevention of this fatal disease is rendered a distinct possibility. It is therefore with much satisfaction we are told that during the forthcoming year part of the grant for scientific purposes will be devoted to further study of the relations which exist between human scarlatina and diseases of animals.

The publication of these reports will doubtless give much impetus to the investigation of animal diseases, and the Local Government Board have conferred a service both on the milk producer and on the milk consumer in making them available for general use. A short account of a paper on the clinical aspects of the disease, by Dr. CAMERON, the medical officer of health for Hendon, is appended to the reports of Mr. POWER and Dr. KLEIN, and the whole is prefaced by some remarks by Dr. BUCHANAN, which will add much to the usefulness of the publication.

Two excellent articles appear this month in the *Contemporary* and *Macmillan* respectively, one on food, the other on feeding. Both are written by laymen, and both exhibit a considerable acquaintance with the subject on which they write. The article in the *Contemporary* deals with the all-important question of a cheap and wholesome meat supply for the people. It is written by the Rev. FREEMAN WILLS, a clergyman, who, finding meat a luxury unknown to many of his parishioners owing to the prohibitive prices charged by the butchers, felt constrained to do something to interfere with this state of semi-starvation. So in order that "the poor seamstress, or the old body supported by the slender wages of her factory-boy son, might have a good meat dinner on Sunday," he determined to become a purveyor of meat in his Finsbury parish. His first butcher's shop was a schoolroom, and a few frozen sheep formed the stock. These had to be procured at least two days beforehand so as to become unthawed and fit for cooking by Sunday. But the chief objection to this arrangement was the difficulty of disposing of the remnants, that remained over when the best parts had been disposed of. It therefore shortly became necessary to open a regular butcher's shop, and at this shop a trade of over fifty pounds a week was soon carried on. So successful did the experiment prove that two other shops were quickly added, and recently a fourth and fifth. We congratulate Mr. WILLS on having inaugurated and carried to a point of complete success a most useful and beneficial work—useful and beneficial not only in social, but also in its moral aspect. Much of the craving for alcoholic drinks amongst our lower classes arises from the want of a sufficiently stimulating food for body and brain; but "meat is dear whilst gin is cheap"; and, as Mr. WILLS remarks, the unsatisfied system craves for something comforting; "so dear butchers make full gin-shops, and the butchers help the publicans." Now that the way has been shown, is it too much to expect that the clergy throughout England will take steps to provide their poorer parishioners with wholesome meat at little above cost price. They may shrink from the encounter with tradesmen, or perhaps think it derogatory to the dignity of their cloth, but they must remember it is part of their pastoral duty.

The article in *Macmillan* is of a different character, though on an allied subject, and the "Philosophy of Diet" is treated by "A Layman" with a pleasant lightness that those who write from a somewhat superficial knowledge often impart to the gravest and driest subjects. Many of his remarks, however, are characterised by a caustic shrewdness well worthy the attention of the profession. With regard to the question he raises respecting the care our ancestors took of their digestion, he thinks that at one time they did so, though at a later period they were sadly reckless in such matters. But this can hardly be attributed to neglect of professional teaching, for if the seventeenth and eighteenth centuries had such prophets as CONARO and CHEYNE, ARBERNETHY and JEPHSON preached strenuously against the dietetic errors prevalent at the commencement of the current century. The writer is hard on those "folk who will not so much as take a pill at their own venture, and never

fulfil an invitation to dinner without a visit to the doctor next morning," and hints that the answer given by his physician to Falstaff through the page would be hardly wise to-day, lest we should hurt the susceptibilities of our patients. But the conditions differ. Falstaff's physician could go no further than inspection, and consequently no further than a declaration that, notwithstanding the water seemed a good water, other diseases might be present that in no way gave indication through the urine. Now, had Falstaff come under the hand of a modern uroscopist, the cause of his disorder would have at once been shown by chemical means, and the diagnosis chronic Bright's disease arrived at, and the old knight's life prolonged by submitting to the dietetic restrictions that would have been imposed. For our own part, when any person finds that "he cannot fulfil an invitation to dinner" without a feeling of discomfort the next morning, we should certainly not drive him from the door as "an inquisitive fool"; not because we "cannot afford to," but simply because we know that simple dyspepsia is often the earliest symptom of chronic disease of the kidneys or of that insidious and now common disorder, diabetes. And although the water to appearance may seem to be a good water, still the application of the heat or copper test may reveal hitherto unsuspected albumen or sugar. Again, too, with regard to the writer's belief that in matters of diet, exercise, and habit a man must be his best physician. We should like to know how and in what manner this experience is to be gained. Take, for instance, a very common example. A medical man tells a patient to live chiefly on milk: in nine cases out of ten the patient will reply, "Oh, but milk always disagrees with me." On inquiry we find that the experience has been founded, perhaps, upon one attempt; a pint of milk may have been taken when thirsty, and, on a stomach unaccustomed to it, have given rise to acidity, griping, and flatulence. But let us instruct the patient to begin with skimmed milk, till the stomach can deal with unskimmed, to add a few drops of lime-water to neutralise any acid that may be developed, and only to take small quantities at a time; we soon find the personal experience reversed, and that milk agrees with nine-tenths and disagrees, perhaps, with only one-tenth, if even with that proportion. Lastly, as to the great panacea—the simple rule of moderation. Who shall define its limits? For whilst some may thrive like CONARO on twelve ounces of solid food, there are others, as PROUT pointed out many years ago who can only attain to moderate longevity by living well, and who, to maintain even an ordinary level of health, have to indulge in large and frequent meals.

OUR own correspondence columns and those of our contemporaries show a considerable amount of dissatisfaction with the readiness of some consultants to receive regular visits from patients who have been referred to them by their usual medical attendants—in other words, to become their ordinary instead of their extraordinary advisers. Mr. KESTEVEN'S letter, which we publish to-day, is in point. To such length has this dissatisfaction grown in some minds, that it has actually been proposed to create "an Association" for all who share it and wish to promote it. This is an age of associations, and one more or less would not make much difference; but we scarcely think that the evil complained of needs an association for its cure, and we have some doubt whether an Association would be the best means of bringing about a better state of things. Let us clearly understand the thing complained of. It is that consulting physicians and surgeons frequently receive patients and treat them as general practitioners. Sometimes small fees are taken. No reference is made to the regular adviser; his co-operation is not sought; he is not informed of the transaction, which, so far from being an individual one, becomes a habit, so that, in respect of the patient, he ceases to be the patient of the general practitioner and becomes that of the consultant. It is said that young consultants are most apt to err in this matter; but they are by no means the only delinquents, and it is alleged, apparently on good grounds, that men of world-wide reputation are not above absorbing a patient altogether and withdrawing him from the care of his family attendant. To state such a case is to condemn the practice complained of. We are not unmindful of the exigencies of young consultants; they never were more numerous, and they certainly never were more meritorious than they are at the present day. London alone would supply young consultants below forty years of age by the dozen, who could give a first-rate opinion or do a capital operation in a first-rate way in almost any case of medicine, surgery, or midwifery. They must live, and they must keep up good establishments; and, as a rule, they are as honourable as they are efficient. We are not prepared to say that they should never see a case independently. Such an absolute dictum would scarcely be found in PERCIVAL, whose chapter "on the conduct of Physicians towards Apothecaries" may always be read with advantage and pleasure. *A fortiori* such an iron rule could not be laid down now; but we are, nevertheless, prepared to say that the young consultants who are most punctilious in cultivating true *consultations*—i.e., the real comparison of notes between the general practitioner on the one hand, and the consultant on the other, and who are most anxious to make the general practitioner a real sharer in the treatment and in the credit of the case—will, in the long run, best promote not only his own interests, but those of his patients and of the public. We shall be excused for reproducing here a few sentences from PERCIVAL, only making this important observation, that the difference in function and in education between the apothecary of his day and the general practitioner of the present all goes to emphasise the duty which this classical author enjoins on physicians in respect of the ordinary advisers of those who consult them:—

"The apothecary is in almost every instance the precursor of the physician, and being acquainted with the rise and progress of the disease, with the hereditary constitution, habits, and disposition of the patient, he may furnish very important information. It is in general therefore expedient—and when health or life are at stake expediency becomes a moral duty—to confer with the apothecary before any decisive plan of treatment is adopted, to hear an account of his whole experience concerning the *juventia* and *incidentia* in the case. Nor should the future attendance of the apothecary be superseded by the physician; for if he be a man of honour, judgment, and propriety of behaviour, he will be a most valuable auxiliary through the whole course of the disorder, by his attention to varying symptoms, by

the enforcement of medical directions, by obviating misapprehension in the patient or his family, by strengthening the authority of the physician, and by being at all times an easy and friendly medium of communication."

Between such physicians and such general practitioners there can be no serious misunderstanding. The limited means of the patient may not always admit of a joint attendance. The patient has undoubtedly the right, too, to take an independent opinion. But such instances will not interfere with the perfect trust which honourable men in different lines of practice place in each other. It must be allowed that there are few absolutely pure consultants in any community—that is to say, few practitioners—who absolutely refuse to prescribe for patients or to give a prescription or opinion without the presence of the regular practitioner. It must also be allowed that in the other direction the line of demarcation between consultants and general practitioners is not sharply defined, and that many general practitioners do a considerable consulting practice. All this does not alter the obligation of the most scrupulous care resting on the physician to uphold the reputation of his professional brother, and, so far as he possibly can, to insist on communicating and co-operating with him in every case, especially in those cases which the said brother has referred to him. The physician or surgeon who can appropriate such cases, or lightly express or listen to any disparagement of the regular adviser, must be indeed defective in his moral constitution. No Association is needed for his condemnation; the unanimous voice of an honourable and united profession pronounces it.

Annotations.

"Ne quid nimis."

HEALTH OF THE TROOPS IN EGYPT.

WHILE we are disposed to exercise considerable reserve in accepting the sensational statements which have appeared in some of the daily papers respecting the excessive rates of sickness and death among the troops serving in Egypt, we have reason to believe that in the frontier field force they have been abnormally high. There is no doubt that enteric fever has prevailed to a very considerable extent, and in a fatal form, among the men on the frontier, and especially at Assouan. The chief factors in this have been the high temperature, the absence of active employment and the consequent continued occupation of an encampment on the same ground, the age of the men composing the force, and probably the emanations from the alluvial soil on the banks of the Nile. We are disposed to think that an undue share of the blame for this unhealthiness has fallen to Assouan, from various circumstances. When the reduction of the force was decided upon the troops from the various outposts were concentrated there, bringing their sick with them. As they were moved onwards, the sick—at least the severe cases—were left behind, and those which terminated fatally were borne upon the reduced strength of the Assouan garrison. The return also, extending over a limited period only, and with a small force, is likely to give rise to an erroneous estimate, owing to the fluctuations which occur under such circumstances. That a heavy death-rate, however, has prevailed since the commencement of the hot season is too true, and the question may be fairly raised, Has it been unavoidable? If the occupation of the frontier by Europeans was a military necessity, it is difficult to see how this unfortunate result could have been altogether prevented. We believe that every reasonable precaution has been taken in the sheltering, clothing, and feeding of the men. The only questions seem to be whether a more healthy place than Assouan could not have been found which would have equally answered the military requirements? and whether every necessary precaution was taken to preserve the men in health when obliged to occupy this unhealthy spot? We have reason to believe that, so far as the medical department has been concerned, this was done; that Surgeon-General Nial has exercised a careful and judicious superintendence over the sanitary arrangements, and that the Director-General has spared no pains to have the recommendations which were brought under his notice efficiently carried out. We have also reason to believe that the recommendation to reduce the number of Europeans and replace them so far as practicable by native troops, when these could be relied upon, was pressed upon the attention of the military authorities on the spot, by whom alone the extent to which such a measure was possible could be determined. The removal to Cyprus of men who have suffered from fever, and who were unable to regain their strength in the place where they became affected, has been sanctioned and carried out freely. We trust that the changes which have been made with this view, and the withdrawal of the men, so far as practicable, from the unhealthy localities, may be found effectual in checking the sickness and mortality, and that it may be possible to replace them by trustworthy Egyptian soldiers, who may probably be better able to resist the local causes of disease.

THIRST AND DRINKING IN HOT WEATHER.

So far as the mere sensation of thirst is concerned, there can be no question that it is a mistake to drink too much or too frequently in hot weather; the fluid taken in is very rapidly thrown out again through the skin in the form of perspiration, and the outflow being promoted by this determination toward the surface, a new and increasing demand for fluid follows rapidly on the successive acts of drinking and perspiring, with the result that "thirst" is made worse by giving way to it. Meanwhile, it must not be forgotten that thirst is Nature's call for fluid to replace that lost by cutaneous exudation in warm weather; and if the demand be not met, what may be regarded as the residual fluid of the tissues must be absorbed or the blood will become unduly concentrated. Now, this absorption of the residual fluid of the tissues has the obvious drawback of taking into the blood in a concentrated instead of a dilute form the products of disassimilation, together with the absorption of some excrementitious matters which would probably not be taken up at all if the blood were not abnormally dense. It is necessary to recognise that harm may be done by a process of self-poisoning with excrementitious matter, retained, or taken up, in default of an adequate supply of fluid in the form of drink to dilute and wash it away. There is, moreover, another disadvantage of the non-drinking method of suppressing thirst. It is especially needful for the preservation of health that the metabolism on which normal nutrition depends should be rapid and free in hot weather. If the organic temperature is, or more accurately if the several and complementary temperatures of the organism are, to be maintained at the health point, tissue-change must be favoured, and such modifications of body-heat as may be effected by flushing and evaporation must be facilitated. In short, if we refuse to drink when we are thirsty simply because we shall thirst again, we are imposing a restraint on the activities by which Nature is endeavouring to preserve the health. We are doing precisely what the irrational homœopaths do, or did, when refusing fluid to cholera patients or limiting the drink of those who

suffer from fever. Of course, like produces like in the matter of thirst from any cause, but the like produced is natural; and it is, or rather was, strange to note that in one of the earliest notorious cases of malpractice by persons calling themselves homœopaths in England the dogma "Similia similibus curantur" should be flung to the winds, and drink refused to a patient dying of liquid diarrhœa, because, forsooth, the taking of fluids increased the diarrhœa and made him more thirsty! We venture to hope that those who are zealously urging the policy of refusing to quench their thirst in this hot weather because "drinking makes people more thirsty" will reconsider their policy from the physiological standpoint, and that they will recognise that to thirst and drink, and perspire and drink again, are the natural steps in a process by which Nature strives to maintain the integrity of those organic changes which the external heat has a tendency to impede. The natural and true policy is to supply an adequate quantity of fluid without excess. Therefore do not abstain from drinking, but drink slowly, so as to allow time for the voice of Nature to cry "Enough." There is no drink so good as *pure* water. For the sake of flavour, and because the vegetable acids are useful, a dash of lemon-juice may be added with advantage. The skin should be kept fairly cool, so that a sufficient quantity of the fluid taken may pass off by the kidney.

THE WIRE SUTURE FOR FRACTURE OF THE PATELLA.

DR. DENNIS, of New York, has published in the *New York Medical Journal* a very vigorous defence of Sir Joseph Lister's practice of wiring together the fragments in cases of transverse fracture of the patella. He points out, by way of introduction, that the birthplace of this operation was America; the earliest recorded case was operated upon by Rhea Barton in 1834; he was followed in 1838 by McClellan; and then, many years later, Cooper, Logan, and Green adopted the method. Dr. Dennis urges that the shortness of the period of treatment, measured by weeks only, the great superiority of result—bony union and a useful joint,—and the proved safety of the operation, are three unanswerable claims in support of this operation. Like all others who have practised this procedure, he lays great stress upon the precision with which all the details of aseptic surgery are carried out, and he urges that only those who are well versed in these details should attempt the operation. The mortality in the last sixty-nine cases collected by him has been at the rate of only 1·4 per cent., and he believes that even this may be diminished. A very useful table of 187 cases is appended to the paper, and a short account is given of many cases under Dr. Dennis's own care. The paper altogether is a valuable contribution to a surgical discussion which is not yet closed.

EXTENSION OF THE CHOLERA PREVALENCE.

LAST week we expressed a fear that with the month of July a change for the worse might be anticipated as regards cholera in Italy. The extension of the disease which we ventured to foretell has already come about, and it is to be feared that it may be but a first step in the direction of a still wider diffusion of the infection. Whilst in Brindisi itself the progress of the disease is steadily maintained, the neighbouring province of Lecce and the surroundings of Brindisi are the subject of a wide diffusion. On July 4th we learnt that in Latiano and Francavilla, with a total population of some 13,000, there had then been 214 cases of cholera with 59 deaths, and on the 6th there were 26 deaths at Latiano, 34 at Francavilla, and 4 at San Vito; and in the province of Lecce the total deaths recorded between June 30th and July 3rd amounted to 290. And whilst this extension has been going on in the south of Italy, the disease still causes a daily fatality in the north. Venice remains infected, and in the neighbouring province of Ferrara, where Codigovo was first attacked, a continuance of the disease is still recorded. And not only so, but Fiume in Austria has received the infection, a daily fatality taking place there. With a continuance of the hot weather this state of affairs can hardly be expected even to remain at a standstill, and hence a further diffusion may at any time be expected.

CONGRESS OF NATURALISTS IN BERLIN.

THIS year's assembly of naturalists and physicians in Berlin (writes our Berlin correspondent) promises to be on a grand scale. It has been decided, I learn, through the initiation of the German Colonial Association, to form a special section for Medical Geography, Climatology, and Hygiene, in which observations and personal experiences made in foreign countries, especially in the tropics, are to be discussed. The German Colonial Association has undertaken to make the necessary preparatory steps. Geheimer Medicinalrath Hirsch is the chairman for the formation of such a section, the co-operation being secured of competent men, who in the general interest would be willing to assist personally at these discussions. The following are the subjects which will occupy the attention of the section: 1. Acclimatisation in general. (*a*) The fitness for acclimatisation of special races; (*b*) Hygiene of the white races in the tropics. 2. Education; capability of training the natives to work. 3. Sanitary and educational statistics in respect of German colonies and dominions under German protection. Professor Waldeyer, chief of the Anatomical Section, has proposed the appointment of a special session for discussing the subject of Gastrula of the Vertebrata, and offers to introduce the debate by a short report on the results of discoveries up to the present time. Professor Hartmann will conduct the investigation of the anatomico-zootomical collections, for which the building of the old Exchange has been chosen.

ERYSIPELAS IN HELSINGFORS.

DR. LINDEN of Helsingfors, who has had opportunities for the observation of a large number (785) of cases of erysipelas in both hospital and private practice during the last few years, has written a paper summarising the results of his experience in Langenbeck's *Archiv*. The disease is, he says, certainly of an infectious character, and therefore it is necessary to isolate erysipelatous patients in a surgical hospital. The duration and severity of the attacks are always greater in buildings containing several such cases. No connexion can be traced between the number of surgical operations and the frequency of erysipelas; and it does not appear that the number of patients in a hospital exerts any influence over the disease. Neither is any effect produced by different seasons of the year, the atmospheric pressure, the quantity of dust in the air, the level of the ground-water, or the strength of the wind. Sudden changes, however, of pressure or temperature seem to favour the development of erysipelas. The development of the traumatic form depends less on the severity of an operation than on the contact of pus and other septic matter with the wound. With regard to the duration of the disease, Dr. Linden's observations correspond closely with those previously published by Rizmann—the mean number of days being 7 when the arm is first attacked, 7·3 when the disease begins in the head, 8·3 when it develops on the legs, and 9·5 when the trunk is first attacked. The duration is unfavourably influenced by the development of the disease after an

operation in weakly patients. Cases of traumatic origin last longer than those which arise idiopathically. Cicatricial tissue is more susceptible to erysipelas than healthy skin; the same may be said of portions of the surface which are subjected to any mechanical pressure. Relapses occurring within two or three months of the original attack usually run a more favourable course than the original attack, but those occurring after seven or eight months' interval are uninfluenced by the first attack. With regard to treatment, Dr. Linden obtained the most satisfactory results from injections of alcohol. He did not, however, find that Huter's plan of injecting an aqueous solution containing only from 2 to 5 per cent. of alcohol was of much use, but employed equal parts of alcohol and water, injecting one to three syringefuls in the same way as carbolic acid is employed hypodermically. As a prophylactic against erysipelas he considers Lister's dressings as of great value.

THE PRINCESS LOUISE AT UNIVERSITY COLLEGE.

If the hospitals of London are neglected by the great mass of the inhabitants, it is certainly not the fault of the Royal Family, the members of which are ever setting a good example by taking a lively personal interest in the welfare of our great medical charities. The kindly visit of the Princess Louise and the Marquis of Lorne to University College on the 2nd inst. will long be gratefully remembered, not only by those who are personally interested in the hospital, but by the inhabitants of the district. Her Royal Highness arrived at the hospital at 11.30, and was received by Mr. Prevost, the treasurer, Dr. Wilson Fox, Mr. Berkeley Hill, and other members of the medical staff, and proceeded to make the tour of the building, visiting all the principal wards, evincing a kindly sympathy in the sufferings of the inmates, and graciously permitting one of the wards to be named the "Princess Louise." The visit to the hospital finished, her Royal Highness crossed over to the College for the purpose of opening a Bazaar held in the grounds for the benefit of the hospital. Here the Princess was received by the Earl of Kimberley, president of the College; Mr. Cohen, the chairman of the Bazaar Committee; Sir Julian Goldsmid; the Dean of the Faculty of Medicine, and other officials; and after a short opening ceremony her Royal Highness proceeded to make the round of the various stalls, and made purchases at most of them. The Princess expressed her gratification at the picturesque and novel appearance presented by the bazaar; and well she might, for the grounds of University College are singularly well fitted for such a purpose, and with the fine portico for an orchestra, and the stalls arranged in a semicircle in front of it, the general appearance was one not soon to be forgotten. It seems impossible to get money for hospitals without some so-called festival, and, in selecting the form of festival to be held, it certainly seems advisable to choose one which is likely to excite a wide-spread and, if possible, also a local feeling for the charity. Such feeling sadly needs rousing in regard to the London hospitals, and in arranging this bazaar the Committee have, we are told, received much gratifying evidence of kindly sentiment towards the charity. It is barely two months since the idea of a bazaar was entertained, but, nevertheless, the influx of articles for sale has been beyond all expectations, and it is pleasant to be able to state that presents have been sent from all parts of the country, and very largely from patients and their friends, who have not forgotten the benefits they have received. Local feeling has also been roused, and many of the merchants and tradesmen of the district manifested great willingness to co-operate. On the second day the hospital was thrown open to those who wished to visit it. Large numbers availed themselves of this opportunity, and it is to be hoped that the actual sight of the good work the hospital is doing will convince some, at least, that it is a sacred duty to support such institutions.

THE HEAT.

It is not really very hot, though we feel it to be so. The truth is that although the natives of, and habitual residents in, this variable climate of ours ought to be especially responsive to changes of external temperature, and to possess the faculty of quickly adapting themselves to its requirements, we do not as a rule enjoy this excellent property of the organism in any remarkable degree. The special disability under which we labour relates to radiation. We are unable to get rid of heat from the skin by simple dispersion. The black man excels us in this respect. His dark skin glows, as it were, with the heat he throws off. A white man, and an Englishman particularly, resorts to the somewhat clumsy physical expedient of cooling himself by evaporation. He perspires heavily, and as the vapour leaves his body its temperature is reduced, or at least kept from rising. The black-skinned man is less dependent on perspiration, and can cover his body with oil, so that cutaneous exhalation is actually impeded, without suffering, simply because the colour of his surface is one which, like the willow pattern plate in the familiar experiment, gives off heat. Again and again the fact we are stating has been questioned; but recently, as scientists are aware, it has been demonstrated. One reason why English people are so ill-prepared to endure either extreme of temperature, although they are accustomed to great and rapid changes, is to be found in the fact that they rely on clothes for heat conservation to an extent and with a constancy in excess of the habit of almost any other people. We "wrap up" and we throw off our clothing more artificially than other folks. The way to develop a faculty of bearing extremes of temperature is to habituate the body to make its own temperature. Those who do not clothe themselves heavily in winter seldom find it necessary to make great changes in their clothing in order to bear the heat of summer.

THE DANGERS OF DUST.

Dirtiness, damp, and dust are potent agencies of disease. Everyone recognises this; but how many fail to adopt its precepts! If there be sermons in stones, surely the summer dust and its dangers would prove a fruitful subject for medical discourse. There is as great a difference between London and country dust as there is between the corresponding muds. Pulverised matter would be harmless enough if it were deprived of its physical property of ready diffusion. The atmosphere is laden and swarms with particulate matter of highly complex nature. Its chief peril to living beings resides in the organic constituents; largely this organic material consists of minute forms of life in a state of latency, only waiting for a spell of heat and moisture and a favourable amount of light, or it may be darkness, to awaken it into activity. The habits of individuals in every class of society, including the "masses," are not calculated to diminish but rather to augment the amount of organic matter in our atmosphere. Mucus, saliva, and humour popularly known as "matter," must be discharged from the mouth and nostrils to the extent of many gallons daily, and not a little of this comes from infective sources; whilst we venture to think that the bulk of it mingles with the dust of our streets and courts. If, as seems not unlikely, consumption is largely caused by "germs," then a very ready theory may be advocated concerning the mode in which the contagium is caught. Who

can estimate the amount of mischief that the shaking of mats may have caused? How many young girls early in the morning on their way to business have, so to speak, received their death-blow whilst inspiring, all unconscious of harm, some of the clouds of dust that every morning greet them? Who can tell? The abatement of this danger and nuisance is a difficulty that almost seems insurmountable. Much may be done by personal habits of prevention.

DR. FLINT'S ADDRESS IN MEDICINE.

ONE of the most remarkable characteristics of the late Dr. Austin Flint was the promptness with which he set about any work he undertook. Accordingly, when he accepted the invitation to deliver the Address in Medicine at the forthcoming meeting of the British Medical Association he prepared the address at once, and it was found all ready for delivery among his papers. The address is published by D. Appleton and Co., having been passed through the press by Dr. Flint's son; accompanying it is a beautiful engraving of the distinguished physician, which is so true to life that all who were privileged with the friendship of Dr. Flint will greatly prize this memorial of him. The address is an attempt to forecast the advances of medicine in the next fifty years. Dr. Flint suggested that organic chemistry will reveal much that is now hidden, and that the application of the telephone and other recently invented electrical machines to medical practice will make our knowledge of disease as portrayed by sound more precise. Advances in bacteriology and in our knowledge of the causes of disease, with a juster view of the value of some of our therapeutic agents, are other gains which seemed to Dr. Flint to be close at hand. He predicted also changes in the style of medical literature—more subdivision and more concentration; changes in medical teaching—less didactic instruction and more demonstration; changes in medical practice—more specialism, which will need to be carefully guarded against the evils attending it. The address is full of interest; great is our regret that its accomplished author was not spared to deliver it, but we are glad that we are permitted to read it. As a literary production it is a worthy close to the many valuable contributions to the literature of medicine by that great and good physician.

POISONING BY PENNY ICES.

ON July 5th an inquest was held at St. Thomas's Hospital on the body of a boy aged eleven who had died at his own home with symptoms of irritant poisoning, alleged to be due to the eating of penny ice creams of which he had partaken three days before. There had been no analysis of the contents of the stomach or intestine, but from the fact that his symptoms commenced soon after he had partaken of ice-cream, or, as it is called in the district, "lemon-jack," and that others who had also eaten of it suffered from similar symptoms, it is fair to presume that the ice-cream was the cause of his death. The verdict returned by the jury was "Death from English cholera," brought on by eating some deleterious matter. In the account of the inquest it is mentioned that there were several persons present whose children were suffering from acute illness after eating ice-cream. This is certainly a case for the investigation of the Public Prosecutor. We know that there has been a large number (twenty to thirty) of patients treated at St. Thomas's Hospital during the last fortnight, all of whom obtained their ices from a particular stall in Lambeth, nearly all of whom presented evidences of irritant poisoning, and at least three were so ill that it was necessary to admit them. Surely this is a case in which the inquest ought to have been further adjourned for the analysis of the contents of the stomach (though at that distance of time the poison would have been probably eliminated), and the examination of others who had also suffered. In THE LANCET for last year, vol. i., p. 1094, we drew attention to a similar outbreak in the same neighbourhood, and due to the same cause, and we repeated the suggestion which we first made as the result of THE LANCET Sanitary Commission in 1879 (see vol. ii., p. 590): that there should be supervision by the local sanitary authorities of the vendors of the creams, and that from time to time chemical examination should be made of samples of what prove occasionally to be very deleterious compounds. We have no analysis of the vomited matters or of the ices, but from the similarity of the symptoms with those exhibited by the patients last year, it is probable that the poison was carbolic acid, which was found in sufficient quantity in more than one case to fully account for the symptoms. The way in which this poison could have been introduced was explained by the fact that it is used in the earlier stages of the manufacture of a preservative material employed by the men to prevent decomposition of the ingredients of the various ices. Either the chemical processes had not been carried out to their full extent, and the solution used contained much free acid, or the acid itself had been employed in mistake. Some weeks ago two children died at Worthing after only a few hours of severe vomiting and purging. A post-mortem examination revealed no sufficient cause of death, and the medical men, it is said, were baffled in trying to assign a name to the disease. No doubt these were cases similar to the others, but even more comparable to a rapid choleraic attack, in which a fatal collapse has forestalled the earliest signs of enteric congestion.

THE DANUBE AND ENTERIC FEVER.

ENTERIC FEVER has recently attacked 183 persons belonging to the garrison of Klosterneuberg, above Vienna, no less than eight officers having been amongst the number. The cause of this alarming state of things appears to be that the sewage of the town, which used to be conveyed direct to the Danube, has of late, in consequence of the new regulations having for their object the purification of the river, been discharged into a stagnant arm of the Danube upon which the town stands; this arm has thus been converted into a sort of open cesspool. The hospital authorities consider the drinking-water is affected, and so they order from 600 to 800 bottles of soda-water for the patients daily. The garrison is being supplied with drinking-water in casks from wells at a distance. The men are, however, to be immediately ordered away to less pestilential localities.

PREHISTORIC DENTISTRY.

DR. MARTER, of Rome, has for some time past been devoting considerable time to examining the skulls in the various museums in Italy, and in Etruscan and Roman tombs; and he has given an account of his investigations in the *Independent Practitioner*. In the ruins of one of the Etruscan tombs, about the date 500 B.C., he found a partial denture. It was an arrangement for holding in position three upper artificial teeth by banding them to the adjoining natural teeth. These teeth were carved out of some large animal's tooth. Another denture found in an old Roman tomb consists of two natural teeth fastened by means of soft gold bands to the contiguous teeth. The most recently opened and oldest Etruscan tomb yet discovered in Italy was lately excavated at Capadimonti; this tomb belongs to the sixth century B.C., and amongst several articles of jewellery a denture, very similar to those above described, was found. Dr. Marter

was unable to discover any stopped teeth, although many cases of caries and other dental diseases presented themselves. It is certain that dentistry must have been extensively practised in the early history of the world, and that gold must have been used largely; otherwise the early Greek or Roman legislators would not have mentioned the matter in the celebrated laws of the twelve tables. Law 5th, de Jure Sacrorum, is as follows:—"Quoi auro dentes vincti sicut in cum ollo sepelire, se frande esto."

POST-GRADUATE COURSES IN SCOTLAND.

THE suggestion has frequently been made that, following the example of our American cousins, the institution of a post-graduate course in Great Britain would be both acceptable and of great utility. It has been left to Scotland to take the first steps towards giving effect to the suggestion; and a conference of representatives of all the medical institutions in Edinburgh was recently held to consider the subject. The result of this meeting was that most of those present expressed their willingness to join in and to further such a scheme, provided that there really appeared to be a general desire on the part of practitioners of medicine that such a course should be inaugurated. Further, it was remitted to a small committee, consisting of the Presidents of the Colleges of Physicians and Surgeons, the Dean of the Faculty of Medicine in the University, with Professor Chiene and Dr. Muirhead as secretaries, to endeavour to ascertain the views of practitioners on the subject, and to make arrangements for a tentative course this autumn, to be held during the last week of September and the first fortnight of October. At Glasgow, too, on the 30th ult., a meeting was held to discuss the question; and, after full consideration of it in all its bearings, it was resolved to leave the matter to individual teachers for the present year; but a committee was appointed to inquire fully into the proposal, to communicate with the local hospital authorities, and to report the result of their investigations to a subsequent meeting. Gentlemen who feel disposed to join the Edinburgh course are requested to communicate with either of the secretaries before the end of the present month in order that definite arrangements may be made. We shall watch with interest this new departure on the part of our Scottish *confrères*.

PRECAUTIONS AGAINST SUNSTROKE.

THE more than genial warmth of the past fortnight has happily been unattended by that train of accidents from sunstroke with which we have been in other seasons but too familiar. We must not, however, on that account conclude that measures of prevention are not yet necessary. A temperature of 80° or rather more in the shade is no contemptible measure of the solar power, and will more than justify such measures. The full meaning of sunstroke is not included in that term. Heatstroke or insolation is a better word, and implies a further peril besides the downward glare of an unclouded sun. The concentrated heat of a close workroom, as well as the exposure incurred by some careless labourers in the open field, may lead to most serious consequences. The exhaustion of work also, particularly if clothing is heavy, is a predisposing condition which should not be lost sight of. Ventilation, regular nutrition, light clothing, and as far as possible remission of the pressure of work, are strongly indicated by the weather conditions under which we are now living, and we therefore venture to impress their importance alike on employers and employed. Beer and other stimulants are hurtful rather than helpful, and the substitution of non-intoxicant cooling drinks for those beverages is a truly scientific and sanitary advance in public taste. Protection of the head is a subject which is now fairly well understood. It should not be forgotten that the neck as well as the cranium requires to be covered. Postmen seem to have some latitude allowed them as to summer head-gear. Soldiers have the white helmet. The police alone are left out of consideration. Will not Sir Charles Warren, who has felt the tropical sun, consider the need of the force now under his command, and advise, if not a lighter form of helmet, the addition of a scarf-puggaree to that now worn?

TRAUMATIC TETANUS TREATED BY REST.

DR. DE RENZI states, in the *Rivista Clinica*, that by treating patients with traumatic tetanus by means of perfect rest he has been able to restore four out of five to health; whereas when treated in other ways these patients usually die in two or three days. He places the case in a special room where absolute silence reigns. Even in the passages leading to it and in the neighbouring wards care is taken to lay down carpets so that no sound shall penetrate the tetanus ward. The door of the latter is of course well oiled, so as to open and shut noiselessly, and the patient's ears are stuffed with cotton-wool, he himself being strictly enjoined not to make the slightest noise. He must, of course, be fed. This has generally been considered impossible, the teeth being clenched and the spasmodic contraction being increased by attempts to masticate. The obstacle may, however, be easily overcome by parting the jaws and introducing liquid food through a curved sound; swallowing is accomplished without difficulty. This method of treating traumatic tetanus has been tried with success by several Italian practitioners—Drs. Pisani, Maragliano, Ria, &c. The only disadvantage is that the affection is sometimes prolonged for two months. It seems to increase in duration as it diminishes in force.

THE NEW MEDICAL ACT AND MEDICAL REGISTRATION.

WE are requested by the Registrar of the General Medical Council to say that, in view of the approaching election of direct representatives to the Council, he is desirous of bringing before the notice of the profession the great importance of due medical registration. According to the Medical Act, 1886, voting-papers will only be sent to those practitioners whose names are on the Medical Register, and they will be forwarded only to the registered addresses. Neglect, therefore, in at once supplying the Registrar with a correct address will probably involve the loss of the practitioner's vote.

"THE RELATION OF INSANITY TO SIN."

IT would have been more accurate to specify crime instead of speaking vaguely of sin. The *Saturday Review*, in an article on this topic, restates and professes to find approximate satisfaction in the familiar legal questions about insanity: "Did he know that what he was doing was wrong? If he did, could he help doing it?" We are unfortunately compelled by the facts of the case to join issue, and contend that a man may know he is doing wrong, and do it without obligation or impulse of any sort, and yet be insane. There is unquestionably such a thing as "moral insanity"—that is, insanity of the conscience of morality; and this particular form of mental disease—for such it is—cannot unhappily be very readily or certainly distinguished from that depravity of the moral sense which characterises alike low developments, and what Herbert Spencer has designated, and Hughlings-Jackson has demonstrated in pathology, as "dissolution." There will be no substantial progress in the study of mental disease until this branch of science is rescued from the toils of the lawyers.

The judges, by their formulation of imperfect views of facts in medicine—and therefore beyond the province of non-medical observers, however able and acute—have done grievous violence to truth and principle, and they have placed a great stumbling-block in the way of the doctors. For the present we must stand on the defensive, and may in all truthfulness be described as lost in amazement at the wondrous and inexplicable folly of those who, while attempting to recognise a disease and to discriminate between it and health, should set themselves against the study of the only methods by which diagnosis, in a medical sense, can be safely or successfully performed.

HOT WEATHER AND STREET HYGIENE.

THE summer having set in with more than its accustomed severity—an energy probably too hot to last,—attention is naturally directed to the condition of our streets and general surroundings, as regarded from a sanitary point of view. Mismanagement is to be expected, and must be endured. In this free country it is the privilege of an enlightened community to hand over its affairs of state and locality severally to the guardianship of authorities, which are purposely composed of amateurs. It is the genius of our English method of rule to be governed by persons who are in no sense professional. We glory in the fact, that, in the main, justice, finance, and politics are administered by men who are not experts. Our First Lord of the Admiralty must on no account be a sailor. Our Secretary of State for War must not be a military man. We prefer a Chancellor of the Exchequer who has not been engaged in the management of any large financial concern. Our bishops are selected by laymen, and it would be considered a disqualification for the chairman of a sanitary board to have any practical trade knowledge of the subjects which the authority is charged to administer. On the whole, doubtless the system which prevails works well. We are spared the nefarious policy of self-seeking, but there are disadvantages arising out of, or accruing to, this recourse to ignorance, as a way of avoiding interested motives and policy, which ought not to be disregarded or held of no account. It is the fashion of the day to impute carelessness to those who wrongly administer public and local affairs. This may be a charitable view of the facts, but it is very far from being an accurate or sound one. We do not think those who hold office in our midst are at all commonly neglectful of their duty. It is much more to the point that they are both fussy and ignorant. They wish to do well, but their want of acquaintance with the subjects on which they are required to pass a judgment misleads them, and leaves them at the mercy of the avowedly interested agents who are selected to work under them. Half a dozen years of government by experts would do this long-suffering country a world of good, though some evils might be inseparable from the good. It is not worth while to particularise the instances of mismanagement in the affairs of health which place the population at a disadvantage. Unemptied dustbins reeking with pestilential filth, because contractors underpay their men and vestries lack the knowledge necessary to make them masters of the situation and able to compel their contractors to discharge their duties; over-watered asphalte and wood pavements, and unwatered macadamised or stone-pitched streets; huge ponds cleaned at the worst possible time, and the neighbourhood poisoned with the putrid mud laid broadcast in the sun; carbolised water left about for children to drink, and the like—are incidents of the administration by unskilled hands on which we especially pride ourselves. If persons who really understood the business in which they were engaged could be placed in authority, these *gaucheries* would cease; but any such selection would have the drawback of introducing the peril that these skilled authorities might take advantage of their position, and turn it to their own benefit, so that we must put up with the dangers to health and the manifold annoyances to which we are subjected.

VESTRIES AND THE REMOVAL OF DUST.

THE example recently set by a resident in Marylebone who failed to procure the removal of house-dust by the parochial authorities, has been followed by a resident in St. George's, Hanover-square, who applied last week to Mr. D'Eyncourt to obtain his assistance to put pressure on the negligent officials. The complainant pathetically stated that he had made application to the vestry without avail, that he had no right to clear the dustbin himself, and that if he did so he was liable to a penalty of £5. The dustmen's aid had been sought; they had been given money, and a subscription had been sent to their beanfeast; what more could a ratepayer do? Mr. D'Eyncourt recommended that the vestry be summoned after seven days' notice had been given them, but he naturally objected to allow the constable to be used as a means of communication to the vestry. If magistrates were to do so, the metropolitan police would soon have to undertake the duty of dust inspectors. The encouragement magistrates are giving to householders is certain sooner or later to bear fruit. Vestries are not, as a rule, very susceptible to public opinion, but a conviction before the magistrate will help, more perhaps than anything else, towards the modification of the system which now exposes the health of the ratepayers to injury.

"MUMMIFYING."

THIS is the not particularly attractive term applied to a process which is alleged to render the animal organism so insensitive as to be almost unaffected by toxic influences, and so stable, or inert, as regards the metabolism of its constituent elements as to need very little sustenance from without. A man named Succi, who lives at Forli in the Romagna, is said to have discovered a "liquor extracted from various herbs" which has this marvellous effect on the bodies of persons taking it, that, as a result of its use, they can almost wholly abstain from food for a lengthened period, and can resist the influence of certain poisons. It cannot, we think, be doubted that ways of reducing the interchange of elements in the organism to an extremely low grade and of collaterally minimising the absorptive powers of the body do exist, and have been known to certain classes, and perhaps small communities of men, from very early times. This being understood we shall regard with tentative interest the investigation said to be in progress with regard to the process and powers of Succi by Professor Peruzzi of Bologna.

DISINFECTION OF RAILWAY CATTLE-TRUCKS.

DR. REDARD, Surgeon-in-Chief to the French Railways has lately presented a detailed report on the disinfection of cattle-trucks to the Government department charged with the railway administration throughout France. After reviewing the cleansing methods adopted in different countries, and recording experiments with chemical antiseptics and disinfectants, Dr. Redard arrives at the following conclusions: Chemical disinfectants are bad microbicides, requiring large quantities and prolonged contact. Spores and germ-corpuscles resist almost all chemical disinfectants. Some substances, which are very active against spores and bacteria, are very frequently powerless against a virus, unless incorporated with it freely and long. Heat is the disinfectant *par excellence*. Numerous experiments with virus and successive inoculations proved that absolute disinfection can only be obtained with certainty with steam superheated

to + 110° C. This is not easy to obtain. The different processes hitherto in use only yield boiling water or steam below 100° C. Dr. Redard therefore proposes to pass the steam through a serpentine coil placed in the locomotive boiler. Steam from 110° to 130° C. may thus be obtained.

THE RECENT LOW DEATH-RATE.

THE recent health of the large town population of England, judged by its death-rate, has been unprecedentedly satisfactory. The mean annual death-rate during the thirteen weeks of last quarter, among the rather more than nine millions of persons estimated to be living in the twenty-eight large English towns dealt with in the Registrar-General's weekly return, did not exceed 18·6 per 1000. This rate was 2·9 below the mean rate in the corresponding periods of the ten years 1876-85, and 2·4 below the mean rate in the four most recent years 1882-85. London has been especially healthy, its death-rate having been so low as 17·2, and considerably lower than in any previous corresponding period on record. The mean rate in the twenty-seven large provincial towns was 19·8 and 2·7 above the rate in London. The death-rate in the whole of England and Wales bears a tolerably constant relation to that of its twenty-eight largest towns, and if the death-rate of the whole country during last quarter bore the same proportion to that of the twenty-eight towns, as it did in the four preceding corresponding periods, it may be estimated that the annual death-rate in England and Wales in the three months ending June last did not exceed 17·1 per 1000. This rate would be considerably lower than that recorded in any previous corresponding period since civil registration was established in 1837, and 4·5 below the mean rate in the second quarters of the forty-six years 1838-84. The constant and increasing decline in the recorded death-rate in England speaks eloquently of the reality of sanitary progress.

PHARMACOGNOSY OF NITRITES.

THE present position of nitrites in medicine was clearly set forth by Mr. Armstrong in a lecture recently given in the materia medica department of the University of Edinburgh. He believes that there are but three compounds worthy of a permanent place in therapeutics—nitrite of amyl for inhalation, nitrite of sodium and nitro-glycerine for administration by the mouth. For subcutaneous injection nitrite of sodium should be preferred. If it were not for the intense headache, not always obviated by custom, that nitro-glycerine causes, certainly it would be most convenient for gastric ingestion, since it is practically stable in all conditions of the stomach. The decomposition of nitrite of sodium by the acid secretions of the stomach may readily be prevented by administering small doses of alkaline salts—the bicarbonate or carbonate of soda.

RUSSIAN PASTEUR INSTITUTES.

THE Odessa Medical Society, having solicited permission from the Minister of the Interior to open a subscription for the Pasteur Institute in Paris, have met with a refusal, the minister considering that all Russian subscriptions should now be applied to the national Pasteur institutes, of which no less than four are being established—viz., one in St. Petersburg, under Drs. Krugelviski and Hollmann; one in Moscow, under Dr. Unkovski; one in Odessa, under Prof. Metschnikoff and Dr. Gamelei; and lastly, one in Saratoff, under Dr. Parschenski. All the above-named physicians have been to Paris and learned the method from Pasteur himself, and a rabbit which has been inoculated with the virus of rabies has been brought back to Russia to serve as a starting-point.

HEALTH ASSURANCE.

THE idea of a fixed payment for medical services is a popular one, and becomes more so as it is debated. To know the worst, and to have no medical bill at Christmas to pay, must be a luxury which medical men are least able to appreciate. The essence of all such schemes, if they are to be successful, must be in their fairness. While really relieving the patient and his family from an onerous liability, they must be considerate of the medical man and secure him a fair remuneration. The fault of most existing Provident systems is that the medical remuneration is altogether inadequate. A system has been formulated by Mr. Fleming Phillips, of St. Mary Bourne, Andover, Hants, which he has stated in circulars. He has two classes—Class A and Class B. The former class is to include those whose wages do not exceed 30s. a week. The fees to be paid per annum per head are from 4s. to 8s., extras excepted viz., midwifery, vaccination certificates, surgical operation, fractures, &c.; medicines included or not, according to agreement. Class B is intended for those of higher means. The fees range from 10s. to 40s. or (rarely) 60s. per annum for each individual. A reduction is made in the rates for more than four persons of one family residing together. Specimen circulars, with explanatory statement, are to be had for a small sum on application to Mr. Phillips. In Class B the variation of rate is according to health, habits, means, &c., at the time of entrance. Extras as above are excepted; distance, too, is to be considered. In the circular sent to patients it is stated that the system does not involve pecuniary gain to the practitioner, and its acceptance is quite optional. Care would have to be taken not to address the circulars to the patients of other men. The fees given seem a fair basis for agreement in the respective classes of cases, and the scheme seems worthy of consideration.

PHOTOGRAPHY AND PATHOLOGY.

WE have before us photographs by Dr. Heneage Gibbes of striped muscle from the water-beetle, of goblet cells from the stomach of the newt, of Niesen's bacillus from a high altitude, of the comma bacillus, of cirrhosis of the liver, and of the cornea stained with gold. It would be difficult to speak too highly of these photographs. The definition of the bacilli and of the goblet cells is very perfect, and that of the striæ of the muscle of the water-beetle exquisite. The coarse photographic representation of morbid structures is assisted by a little colouring, and is most effective. Three such plates are before us, one representing cancer of the lung in a most vivid and beautiful way, the others, pericarditis and mitral disease respectively. It looks as if from this branch of art we should have much help in the future.

A MEDICAL ASSOCIATION FOR NEW ZEALAND.

IN response to a circular letter addressed to the various medical societies in Auckland, Wellington, Canterbury, and Otago, a meeting was recently held at the Dunedin Hospital, for the purpose of forming a general Medical Association for New Zealand. Several delegates having expressed their views, it was unanimously resolved that an Association be formed, having for its object the promotion of medical and the allied sciences, and the maintenance of the honour and the interests of the medical profession. At an adjourned meeting of the delegates, resolutions were passed calling the attention of the Government to the gradual and persistent increase of puerperal fever in various parts of the colony, and the necessity for instituting some form of registration for midwives, and protesting against the action of the Legislature in taking away the office of coroner from medical men in active practice. The Association has a wide

field for its labours, and one of the chief ends to which its efforts should be directed is a reform of the law relating to the registration of medical practitioners. This, we may confidently assume, will occupy to a large extent the deliberations of the Council, deliberations which we trust may result in success.

DR. WILHELM FROEBELIUS.

THE death is announced, in the Russian papers, of Dr. Wilhelm Froebelius, formerly a great ophthalmic surgeon in St. Petersburg. When ophthalmoscopy was in its infancy Dr. Froebelius wrote largely on the subject, and he was the first to perform iridectomy for glaucoma in St. Petersburg in 1857. He was appointed inspecting officer to the foundling institutions in 1864, and gathered under him a number of young subordinates of great ability and scientific attainments, who have rendered the greatest service to the important establishments committed to their charge; he obtained the appointment of a prosector, the first of these officers in the country. He also established, as early as 1866, an institution in St. Petersburg for calf lymph vaccination.

FALLACIOUS SURGICAL STATISTICS.

La Gazzetta degli Ospitali (June 30th) concludes a series of articles on eight years' work in the surgical clinique of Pavia (1877-85), with a summary showing 58 deaths in 1098 operations—a mean mortality of 5·28 per cent. How little importance can be attached to such a general average may be deduced from these facts: 21 cystotomies were performed without a death; so with 41 amputations of the limbs, of which 18 were of the leg and 8 of the thigh. But 11 of 39 patients succumbed after extirpation of goitre, and 17 of 34 after the following gynæcological operations: extirpation of the uterus by laparotomy, 2 cases, 2 deaths; extirpation of the uterus per vaginam, 10 cases, 4 deaths; 3 laparotomies for solid uterine tumours, with 3 deaths; 19 ovariotomies, with 8 deaths.

FOREIGN PROFESSORSHIPS.

DR. F. FALK has been appointed Extraordinary Professor of State Medicine in Berlin. Dr. C. von Rzehaczek is retiring from the Professorship of Surgery in Graz. Prof. Späth of Vienna having retired, Dr. Breisky, the well-known gynæcologist of Prague, has been appointed to succeed him. Dr. Breisky's claims were so universally recognised that no other candidate ventured to appear in the field. He was Professor of Gynæcology in Berne from 1867 to 1874, when he received a call to his present post in Prague. Dr. Gustav Braun, one of the Professors of Midwifery in Vienna, has been given the title of Hofrath. Dr. Kaulisch, Professor of Internal Medicine in the German Faculty of Prague, has died at Giesshübl, at the age of fifty-six.

BLINDNESS DUE TO DECAYED TEETH.

DR. WIDMARK, a Swedish surgeon, having as a patient a young girl in whom he was unable to detect the slightest pathological changes in the right eye, but who was yet completely blind on that side, observing considerable defects in the teeth, sent her to M. Skogsborg, a dental surgeon, who found that all the upper and lower molars were completely decayed, and that in many of them the roots were inflamed. He extracted the remains of the molars on the right side and in four days' time the sight of the right eye began to return, and on the eleventh day after the extraction of the teeth it had become quite normal. The diseased fangs on the other side were subsequently removed, lest they should cause a return of the ophthalmic affection.

ELECTION DIFFICULTIES.

THE difficulties which beset the practice of indicating by means of voting-papers the preference of an elector for a particular candidate for a vacant office are seemingly too much, not only for poor Hodge, but for persons so superior to him in position and education as Masters in Arts, Laws, and Science. Or is a contempt for trifling details to be regarded as the explanation of the remarkable fact, mentioned in our report last week of the meeting of Convocation of the University of London on Tuesday, that, in recording their choice of a candidate for the Senate, no fewer than 114 of the members' voting-papers were rendered invalid by informality?

AMERICAN DENTAL LEGISLATION.

THE following Bill has been introduced in the New York Legislature:—"Sec. 1: A dentist who shall administer chloroform or ether to any person, unless said dentist shall be a regularly graduated physician from some legally incorporated school of medicine and surgery, is guilty of a misdemeanor. Sec. 2: This Act shall take effect on and after September 1st, 1886."

THE DIRECT REPRESENTATION OF THE PROFESSION.

SEVERAL names have been mentioned as those of practitioners willing to act as Direct Representatives of the Profession in the Medical Council in Ireland, and also in England. So far we have not heard of Scotland. In the absence of formal nominations, and considering the shortness of the time that has elapsed since the passing of the Act, we think it premature to publish announcements of candidatures.

POISONOUS HONEY.

Il Morgagni reports that at the last meeting of the Agricultural Society of Dresden, M. Bley made a communication on the poisoned honey frequently imported from Trebizond. Stramonium grows there spontaneously, and, being taken up by the bees, poisons the honey, which is afterwards exported. Resulting cases of disease—some with fatal issue—have been officially certified. In American honey, also, some poisonous principles have been found, gelseminum especially.

THE Jaffa Suliman Dispensary, instituted and sustained by the Medical Women for India Fund, appears to be in full work. During 1885 no less than 27,429 patients attended and received medical relief. But the resources were inadequate to the demands made upon the charity, and accordingly a small temporary hospital at Khetwady was opened in April last year, and with the aid of a Government subsidy was got into working order. If Mr. Thornton's statement at the annual meeting of the National Indian Association be anywhere near the truth—viz., that of the 1,500,000 patients who received medical aid at the different hospitals and dispensaries of the Punjab in 1884 only one-fifth were female,—the justification for the provision of such institutions as the Jaffa Suliman Dispensary and the Khetwady Hospital must be regarded as complete.

AT the forthcoming meeting of the British Association Lord Rayleigh will open a discussion on the Physical and Physiological Theories respecting Colour Vision, and Dr. Michael Foster will probably be one of the speakers.

DR. IRELAND'S book, "The Blot upon the Brain," is, we understand, to be translated into German. The French translation is reported to be almost finished.

THE PRESENT ASPECT OF THE CHOLERA QUESTION.

BY PROF. DR. MAX VON PETTENKOFER,
OF MUNICH.
Abstract supplied, by special permission of the Author, by
HENRY KOPLIK,
OF NEW YORK.

(*Concluded from page 30.*)

HIRSCH, in his work on Historico-Geographic Pathology, has collected a number of facts concerning the Indian epidemics which speak as much in favour of the influence of human intercourse as they do for that of *time* and *locality*. The epidemiological facts connected with the course of cholera through long intervals of time and over wide tracts of land show that the spread of the specific cause of cholera through Europe is clearly connected with human intercourse, for in no other way could we explain how the disease has wandered in different directions from India step by step, and why so great a time was included in this spread of the disease. Yet human intercourse does not account for everything in this connexion; time and locality also play an important *rôle* in this question. The author lays especial stress on the two latter conditions, and endeavours to explain through them the diversity of epidemics in time and place of occurrence. The Contagionists, in rejecting the influence of time and locality, are as one-sided as the Autochthonists, who reject entirely the facts speaking for the influence of human intercourse.

1. *Infection of the healthy by the sick.*—Contrary to what is found to be true in the case of entogenic infectious diseases (small-pox, typhus, and scarlet fever), physicians in constant attendance on cholera patients are not attacked by the disease more frequently than others who are not. This same phenomenon has been observed among the nursing staff. If cholera were contagious in an entogenic sense, these persons should show a greater mortality than others. The researches of Günther, Bouchardt, Kopp, and Ricord support the above fact. Prof. Pettenkofer has found that in the epidemic in Munich the nurses also were as little subject to the disease as the physicians, though they came in much closer contact with the patients. The nurses, or other persons who are in the vicinity of the patients, become sick, not from an entogenic infectious matter, but from an ectogenic matter, which either develops in the locality itself or is brought by the patient on his person in sufficient quantity from the cholera district. That intercourse with the patient cannot be regarded as a source of infection shows itself most plainly in India among the nursing *personnel*. The explanation offered in the Berlin Conference of the fact that the nurses had perhaps acquired a certain immunity and protection against the disease from their being natives is inadmissible, inasmuch as natives outside the hospitals not in contact with patients fell victims to the disease. If the nurses became the victims of the disease (which occasionally happened), its spread among them was checked, not by disinfection, but by *changing the locality* of the hospital. Virchow (as contagionist) cited a case at the Berlin Congress which showed that a patient suffering from cholera infected also his three nurses. These nurses, however, might have been infected from ectogenic matter adhering to the body of the patient; or, again, the above facts do not exclude also the probability that the nurses may have been subjected to the same influences to which their patient was, and thus have contracted the disease. The vast number of facts given us by the history of epidemics in Europe and India (Cunningham) cannot be put aside by exceptional picked cases. If in most cases the physicians and nurses are not attacked by the disease, it must be because the cholera patient produces nothing in itself infectious (entogen), and the exceptional cases of infection can be explained by assuming that the patients in these instances have brought from the cholera district an ectogenic matter on their persons, which, developing in the new locality, spreads the disease.

2. *The excrement of the patients as the seat of infectious matter.*—If the cholera patient himself cannot in an entogenic sense produce anything to convey the disease, his excretions also certainly cannot. It is to be expected that, as the intestinal tract is the seat of the principal phenomena of the disease, the stools should be found to contain infectious matter. Professor Pettenkofer himself once believed that the stools, if not immediately the seat of infectious matter, could become so by subsequent development in waterclosets and drains. The experiments of Burdon-Sanderson and Thiersch seemed to support this view. Koch also has recently discovered that a constant element in the stools of cholera patients was a bacterium (comma bacillus). But if we go over the history of epidemics in former times, we see, by the light of present bacteriological researches, that the careful disinfection with iron sulphate and carbolic acid was powerless to carry out its professed object; the vitality of certain micro-organisms is not annulled by these agents. The vaunted control of certain epidemics by these agents must have been illusory. The limitation of the epidemics must have been due, in the light of present knowledge, to other more potent agencies not at the time understood. Moreover, in draining cholera localities the excrements of cholera patients must necessarily have passed through large tracts of country, yet no infection has been seen to take place along the direction of such drainage (India). Patients passing through towns have, though suffering from cholera, stopped at hotels and inns, and no cholera has been found to exist along their route. The author, therefore, though accepting the existence of a bacillus, x, entogenic in its nature, as the exciting cause of infection, does not admit the entogenic doctrine of Koch concerning the cholera bacillus. The ectogenic nature of the bacterium, x, is proved by its disposition to develop under favourable conditions of time and locality. Professor Pettenkofer does not accept the diblastic theory of Naegeli, which supposes that infectious diseases dependent on the circumstance of time and locality are due to the action of two micro-organisms, x and y, x being that emanating from the patient, and y being produced by the locality. The combination of the two in the human economy is the cause of the disease. By having lived in a locality containing y, a disposed subject can be infected by x, and *vice versâ*. The author is rather monoblastic in his belief, and believes that the bacterium x, of an ectogenic nature in cases of cholera, is spread by human intercourse.

3. *Hospital and barrack epidemics as a proof of the contagiousness of cholera.*—In spite of the universally observed fact that comparatively few physicians and nurses, in their attendance on the sick, contract cholera, the probability of the disease being contracted through this avenue has become more and more feared. This has led to the construction of separate hospitals for cholera patients. True it is that Griesinger's statistics show in Moscow a mortality of from 30 to 40 per cent. among the nursing staff in 1830, whereas in the city the mortality was 3 per cent. of the population. Romberg's hospital in Berlin shows in 1831 a mortality of almost 50 per cent. among the nursing staff. In the Paris Charité, in 1849, the deaths amounted to 16⅔ per cent., whereas 40 per cent. of the population died. The hospitals in Milan, Toulon, and Vienna also show an increased rate of mortality among the nurses. In Munich certain hospitals in particular localities show an increased death-rate among the nurses. In the case of the latter the author shows that these hospitals were situated in those parts of the city where cholera was also epidemic at the time. Other hospitals in Munich situated outside of these localities showed no mortality at all among the nurses, though they were in constant attendance on cholera patients. In both sets of hospitals the same variety of patients existed, also the same conditions of cleanliness and disinfection. The same order of nuns officiated as nurses in both. Porta supports the author in the above facts. If in Moscow and other cities the hospital nurses show such a rate of mortality, the cause must be sought, not in the patients, but in the *situation* of the hospital. The hospital situated in a cholera locality becomes, with all its inmates, subject to the same influences as other houses and their inmates in these localities. If the hospital is not a "cholera house," the patients will not be a menace to the nursing staff. Bryden has proved this to be the case with India. By studying the history of the spread of cholera in barracks in Munich, Professor Pettenkofer has found the same conditions to hold true as in the case of hospitals. Barracks and hospitals, moreover, situated in cholera districts showed the same course of the disease among themselves as was the case with houses outside the hospitals, but also situated in these districts.

4. *The linen of cholera patients as a source of infection.*—If we believe that the excrement of cholera patients is a source of infection, we must also believe that clothing soiled with the same is a source of infection. Professor Pettenkofer, in 1854, himself called attention to facts which would seem to strengthen the belief that soiled clothing is an entogenic source of infection. Koch, in explaining the striking immunity of Lyons from cholera, attributes this to the fact that the clothing is not washed in the city, but in booths situated on the banks of the Seine and Rhone. But in Zurich, Vienna, and other places, where similar conditions exist, no such immunity from cholera has been observed. Koch also traces the cholera epidemic in the washing village of Capronne to soiled clothing of cholera patients—refugees from Marseilles to Lyons. But at this time there were about 1000 cases of cholera in the city of Lyons; and it is possible also that the epidemic in Capronne was due, not to the stained linen in an entogenic sense, but to a something adhering to the linen which, ectogenic in its nature, was thus conveyed from Lyons to Capronne. Moreover, such carriers of germs may be other articles than linen. It is not an absolute condition that such clothes be washed by others to convey the disease. Cases exist where clothes simply handled in *localities* and at *times* favourably disposed have conveyed the disease. If sick persons coming from cholera districts have proved more infecting than healthy persons coming from the same places, it must be because the sick person has come into closer contact with the local ectogenic infectious matter. But healthy persons coming from cholera districts may also be carriers of this infectious matter. Drasche, more a clinician than an epidemiologist, cites cases where epidemics resulted from washing infected clothing, but which seem to be only hospital epidemics not connected with infected linen. The author, while admitting that clothes from cholera districts can cause "sporadic infections," denies that epidemics can result from such cause alone. In this connexion the author cannot agree with those—as Drasche and Mouad—who attribute such a short period of incubation to cholera as half an hour. In 1854 this question, considered in Munich epidemiologically, was divided into two varieties of cases: (*a*) A person coming from a locality free from cholera to an infected spot was attacked within from two and a half to five days. (*b*) A person coming from a cholera district to one free from it, the next case resulting appeared within six or seven days.

5. *Cholera on ships.*—It has been proved that epidemics do not result where one or two isolated cases come from a cholera district to a locality free from the disease. We may suppose in such cases that the patients bring from the infected localities sufficient germs to communicate the disease to two or three others in the new locality, but the infectious matter (ectogen), not finding a suitable soil, does not thrive, and dies out, hence no general infection. Therefore it follows that the cases of cholera in the new locality were not infected by anything produced by the cholera patients there, but by the original infectious material brought from the cholera district. Such protected spots are naturally ships, and the author has always classed these among the localities unfavourably disposed to the development of the cholera germs. Ships in cholera districts have cholera on board, both where persons have come on board from the infected districts, and also where the patients have not been in such districts. Bryson shows that where ships have for a time been in the cholera district the disease has ceased to spread on board as soon as the ships have left these localities. Therefore when ships with cholera on board set sail for open sea the disease does not become epidemic, but remains limited to one or two cases. If such ships return to the cholera localities the disease also reappears (*Caledonia, Queen, Bellerophon*). According to Macpherson, ships sailing up the Hooghly and Ganges frequently have cholera on board when passing the cholera banks (one or more cases), but as soon as the ship reaches open sea the disease disappears. That ships are bad soil for the development of cholera is shown by the fact that only 11 per cent. of the ships leaving cholera ports have cases of the disease on board subsequently. The mortality on shipboard is only 1·22 per cent. (Robert Lawson). Cunningham and Lawson explain the occurrence of cholera on ships, not by the infection of the healthy through the sick, but by the supposition that something is brought from the land on shipboard, and here develops or comes in contact with those on board who have not been in the cholera districts. In this connexion it would be interesting to call attention to the fact that Cunningham records that from 1861 to 1869, of 129 ships sailing from Calcutta, carrying 50,604 natives to America, in only twenty of them (16 per cent.) did cholera appear, and on only two ships were there more than five cases of cholera during the voyage. In the year 1873, which was a cholera year, not merely for India but also for Europe and America, we have the following statistics. In this year about 400 ships brought 152,135 persons from cholera-infected districts and localities of Europe to New York. Only *four* of these ships had cholera on board. An interesting instance of these four is the *Westphalia* from Hamburg to New York. On her journey two persons died with cholera. On her arrival in New York only nine cases of cholera were found on board; of these eight recovered subsequently in the quarantine hospital. All the eleven cases of this ship belonged to one family. Another interesting case, for a long time unexplained, is that of the war-ship *Britannia*. The war fleets of the United Powers—England, France, Italy, Turkey—lying in the vicinity of Varna (1854) were visited by cholera. The French frigate *Ville de Paris* and the *Britannia* had a large number of cases on board. The English ship, wishing to check the spread of the disease, sailed for open sea; but the disease continued its severity, and in one night fifty cases of death were recorded. It was only after the ship had returned to Varna (where the cholera was at the time) and had transferred the troops and men to other ships that the disease seemed to become less severe, and then ceased without spreading further. The officers of the *Britannia* remained free from the disease. The immense mortality in one night was for a long time attributed to the fact that during the night the companion-ways were all closed, and, the air being very close, the disease was thought to have a favourable soil for its spread among the crew. But investigation has shown that the crew of this ship had probably most of them visited the sailor resorts in Varna, there came in contact with the infectious matter, conveyed it on board, and then became sick with cholera, as the fugitives from other cholera districts are on land. The officers of the ship, not having frequented the resorts or cholera localities, remained free from the disease. That cholera finds an unfavourable soil on shipboard can scarcely be denied. The cargo of the ship also might be a means by which infectious matter is conveyed on board. Bad ventilation, uncleanliness, soiled linen, and cholera stools are not sufficient to explain the spread of cholera on shipboard, for cholera exists on ships where, as in the *Windsor Castle*, the hygienic conditions were all that could be desired. Ballast in the form of soil and sand may be regarded as the carriers of harmful matter, but ships themselves cannot be looked on as the carriers of infection. Koch and Virchow do not agree with the above views. The former, in support of the entogenic theory, shows that cholera is more frequent on transport ships than on merchantmen. But Professor Pettenkofer explains this apparent frequency by the fact that on merchantmen we are less likely to find the disease, in itself not frequent on shipboard, inasmuch as we have here a vastly smaller number of persons than on the transport ships; hence in the latter we are more likely to meet with instances of the disease. Cholera epidemics on shipboard are the exception.

6. *Spread of cholera through human intercourse on land.*—The Autochthonists do not believe in or admit the agency of human intercourse in the spread of cholera on land. Cunningham records that in India pilgrims very often travel in different directions from cholera-infected spots, and some die on their journey. But, independently of this fact, the epidemics always take a certain route. In places lying outside the line of route the cholera patients cause no epidemics, but in the epidemic direction they appear to be infectious. In studying the map of Europe, we find that the cholera epidemics do not in the least spread in the lines of travel. If we were to make a topographical map of the cholera in Europe from 1830-85, as Rheinhard and Günther have done for Saxony, we should see that cholera only favours special localities and avoids others. Railroads have changed nothing in the direction of the spread of cholera either in India or Europe. Nor does the cholera spread any more rapidly to-day than in the days previous to the introduction of railroads. Cunningham in India and Günther and Rheinhard in Saxony have shown that cholera does not spread in the direction of the railway network. If a person comes from a cholera district to one not infected, and cases

follow his arrival in the new locality, or even when epidemics result, it does not follow that this original case is the cause. The arrival of the first case and the outbreak of cholera in the new locality may be simply accidental, or be due to germs carried into this locality at another time and until now latent. The mobilisation of troops in a cholera locality, combined with the want which they bring with them, and also the consequent concentration of masses of people, tend to raise the death-rate, but the spread of cholera is not due wholly to this cause. In 1866 countries harbouring no troops were the seat of cholera, more so in some cases than localities in which cholera-affected troops were quartered. Moreover, following the line of march of cholera-affected troops through a series of forty towns, it was found that only four of these subsequently became the seat of epidemics; in others the disease appeared sporadically, and in twenty-three not at all. It is only where the cholera germ finds a favourable soil that it develops and causes an epidemic. That intercourse has some influence in the spread of cholera is not denied by the author. It has not the great influence attributed to it by the Contagionists.

ADDRESS

DELIVERED AT

ST. MARY'S HOSPITAL,

AT THE

Presentation of Prizes, June 28th, 1886,

BY THE VERY REV. THE DEAN OF GLOUCESTER, D.D.
(DR. BUTLER.)

GENTLEMEN,—It must be the desire of any man who is honoured by the commission which I hold to day to say something which may be useful as well as acceptable to his audience. If you were listening to some member of your own great profession, you would doubtless expect some addition to your knowledge, derived from his insight and experience. You will now of course expect no such benefit. I have nothing to tell you that you do not know already. If I am able in any way to interest you, it will be because sympathy and respect can never be wholly disagreeable to those who receive them. Let me, then, at once try to find out at least one topic common to us all. My experience of life has lain chiefly with the young. I love to think of young men at the beginning of their career, while still a little "sicklied o'er" with the pallor of "hope deferred," and before they become too rudely embrowned by the sun of assured success. They are less interesting to me in what Mr. Canning calls "the brightness of meridian glory" than when for the time a cloud seems to brood on their imaginations and their hopes.

The keen interest of biographies lies not so much in tracing how men of genius find themselves gradually forming an "environment" exactly fitted to their gifts, as in noting how they develop gifts which were not originally conspicuous; how a sense of duty, or of ambition, or of sheer professional perseverance brings out powers of which they were almost unconscious. No doubt there is a pleasure in seeing genius move calmly and swiftly to its recognised goal. We like to read of the young Correggio standing before a masterpiece of Raphael and muttering to himself, with the consciousness of power, "I, too, am a painter." We like to read of Sheridan, after one of his early failures in the House of Commons, striking his head and saying, "I have got it in me, and, by Heaven! it shall come out." But I confess I find something even more stimulating in reading—first, the humorous praise given by a surgeon of St. Thomas's Hospital to Sir Astley Cooper: "Sir, it is of no consequence what instrument Mr. Cooper uses—they are all alike to him; and I verily believe he could operate as easily with an oyster-knife as the best bit of cutlery in Laundy's shop." I like to compare this fervid eulogy—not perhaps to be taken quite literally—with what Sir Astley wrote of himself and left among his private papers: "Sir Astley Cooper was a good anatomist, but never was a good operator where delicacy was required. He felt too much before he began ever to make a perfect operator." Have we here simply the unconsciousness of genius, the self-ignorance of an artist whose ideal of excellence is surpassingly high and exacting? or was this great surgeon really right in his estimate of his own natural powers; as right and as instructive as Brodie afterwards, who in his Autobiography—a twenty years' favourite of mine—has told us this strange story: "A friend of mine, a craniologist, told me that he saw I had the organ of constructiveness much developed, and that this explained how I excelled in the use of my hands, and was an excellent dissector. There was never," says Brodie, "a greater mistake. I was naturally very clumsy in the use of my hands, and it was only by taking great pains with myself that I became at all otherwise."

Gentlemen, I a little hesitate to draw the moral from this candid avowal. I hardly like to conceive of it as even possible that anyone here may say, "I am naturally clumsy in the use of my hands"; but if there be such a man I would dare to say to him, Let not his diffidence be too much for his ambition. Let him not exaggerate the sentiment of pity for those unknown sufferers whom in self-accusing moments he would call his victims. Nay, let not the very irksomeness of the pursuit have too depressing an effect on his spirits, for has not Brodie said, again, that those who succeed best in a profession are those who have embarked in it not from irresistible prepossession, but perhaps for some accidental circumstance, and persevere as a matter of duty, or because they have nothing better to do? "They often," he adds, "feel their new pursuit to be unattractive enough in the beginning; but as they go on and acquire knowledge, and find that they obtain some degree of credit, they become every day more interested in what they are about." But enough upon this head. Let me carry you away, gentlemen, however suddenly, from the reverie of early depression to the heyday of recognised fame and usefulness, and let me bring the physician before you in another aspect.

What rich opportunities does the physician enjoy for the study of his fellow-creatures! I am thinking, of course, of the confidential relations between doctors and the families of their patients. The ear of the physician is the modern confessional. Who is afraid to trust him, if he be worthy of trust? What insight he gains into family histories, into the causes which prevent men from being of one mind in a house, of the secret humiliations concealed beneath a bold front, of the patient heroisms, of the unsuspected sins and even crimes, of the daily tragedies under roofs which to the world at large seem a very temple of prosperity. The thought that I would endeavour to leave with you, my younger friends, is this: If such is to be your position hereafter, what manner of persons ought you to be now in preparing yourselves for so high a trust? The qualifications for such an office are clearly not professional alone, unless, indeed, you are bent on demanding for "professional" training a range and a latitude ideal rather than conventional; unless, just as Cicero claimed for his ideal orator every branch of learning and every intellectual accomplishment, you are prepared to claim for the ideal physician not only all that gives richness to the intellect, but all that gives grace and beauty to moral worth. For, consider how much is required by one who is to be the confidential friend and almost confessor of hundreds of families. He must have in a high degree the gift of sympathy first implanted by nature and then systematically trained. He must have, further, wide knowledge of the world, a clear and sober judgment, an acute moral sense, and an absolute rectitude of purpose. Further, he must have the gifts which attract and inspire affection. Much of the power which doctors so happily wield in families is, I cannot doubt, to be set down to the gentleness of their manners. I suppose, my friends, we are all more or less rough at some part of our lives, and it would be strange if this moral hirsuteness, often found among the young in all departments of study, were conspicuous by its total absence in the student of medicine. The Lord Chesterfield of the hospital is perhaps seldom matured before twenty-two. Unlike the poet, "fit, non nascitur." But it is rare, I think, to find other than gentleness in the adult physician and surgeon, though there have been, and may again be, Abernethys and Jephsons. Gentleness may fairly be termed a characteristic—if you like, an acquired instinct—of your profession. I read of one whom you regard as one of the chief ornaments of your profession. "His manner in ordinary society was sometimes complained of as harsh or abrupt, and he certainly was occasionally neglectful of the mere trifling courtesies of life, and sometimes careless of refinement of punctilio. ..... *But*"—and this is what I love to read of so

strong and true a man—"but in the proper and trying scene of the labours of the medical man, in the chamber of the sick, he was *gentle* as he was resolute. He never had a patient who was not anxious to become a friend, and the voice which was sometimes discordant amid the petty annoyances of daily life was music to a sick man's ear. Into the scene of suffering he never brought a harsh word or an unkind look." This, as I dare say many of you know, was the great operator, Robert Liston.

Gentlemen, there are just two further points on which I shall ask your permission to say a few words, and I am bound to admit that they have the smallest possible connexion with each other. The first is the importance of storing facts as we pass through life; the other is the way of dealing with one important class of facts—our own mistakes. The careful storing of facts is, I presume, one chief characteristic of the philosophic mind. Most of us let facts, whether facts of nature or facts of life, come and go unobserved. We have no microscope ready, and no journal. We were not prepared for them by any previous thought, and therefore they laid no finger upon us. Doubtless, in the medical profession, as in every other body of students, some able men are more distinguished for their extempore acumen, and others for their careful research. In reading the lives of eminent doctors, one notes with delight how one after another is distinguished by this truly Baconian passion—the passion for the accumulation of facts, facts which they have themselves seen with their own eyes and noted down with their own pen or pencil. I am almost ashamed to cite any of those illustrious names which must be so familiar to you, but you must allow something for the naive admiration of a novice. When the great Harvey, at the desire of Charles I., accompanied Lord Arundel on his embassy to the Emperor of Germany, we get this pleasant glimpse of him from an artist who was one of the party: "He would still be making of excursions into the wood, making observations of strange trees, plants, earths, &c., and sometimes like to be lost; so that my Lord Ambassador would be really angry with him, for there was not only danger of wild beasts, but of thieves." Then, again, we have Sydenham showing in his lively way, by his perilous gift of irony, so fatal to a man's prospects until he has turned sixty, his contempt for mere book-learning as compared with actual experiment. Jenner, again, the great and guileless Jenner, whose statue is one of the ornaments of my own cathedral at Gloucester, and whose spirit seems once more needed among us to save us from a dire apostacy—of Jenner we are told: "He was ever observant of natural phenomena; the objects of his studies generally lay scattered around him" in his room. "He had accumulated a great store of original observations." Of Dr. Bright, again, it is recorded that "he always took careful notes and often made drawings." In like manner, Dr. Chambers, "both at the hospital and in private practice, personally recorded the particulars of every case that he saw. Yet once more. Listen to the words of one who can never be listened to without respect—I mean Sir James Paget. This is how he describes what he calls "the simplicity of John Hunter's ordinary method of work": "It consisted mainly in the orderly accumulation of facts from every source, of every kind, and building them up in the simplest inductions. I know no instance so striking as in him of the living force which there is in facts when they are stored in a thoughtful mind." And yet further: "I think it would be difficult to find in all the masses of facts which he has recorded any one which was either observed or recorded erroneously."

A few concluding words on the other topic to which I have referred, and I release you, gentlemen, from this too-prolonged demand on your courteous attention. How to deal with one's mistakes is a problem on which one would have been glad of a little guidance from a Montaigne, or an Addison, or a Charles Lamb, or a Dr. John Brown. Some of us are blind to our mistakes; we do not see them or suspect them. Others are but too well aware of them, but try to conceal them and even to avoid thinking of them. Others, of a nobler order, make it part of their self-training in truthfulness both to see and to admit. Permit me to read you a sentence from Brodie's very interesting Autobiography, which, as I before said, has been with me a twenty years' favourite. He is speaking of what he owes to St. George's Hospital, where he was assistant-surgeon for fourteen years, and then surgeon for nearly eighteen years: "Some of my happiest hours," he says -and how many great surgeons and great physicians will echo his words,--"were those during which I was occupied in the wards with my pupils around me, answering their inquiries, explaining the cases to them at the bedside of the patients, informing them as to the grounds on which I formed my diagnosis, and my reasons for the treatment which I employed, and not concealing from them my own oversights and errors; and all this to kind and willing and only too partial listeners." In his lectures he was equally unsparing towards his own and others' errors. "Not concealing from them my oversights and errors"—that is the sentence which interests me. There, I venture to say, lay the chief moral value of the lecture, and doubtless much of its professional value also. The man who could be thus frank in the exposure of his own errors must have been a superior man. He had learnt much, at least, of the lifelong problem, "how to deal with our mistakes."

And now, gentlemen, in taking my leave of you I cannot but be painfully aware of the thinness of the metal which has been beaten out in your presence during the last half-hour. What I had to say to you amounts to little more than this: Be hopeful; be worthy of confidence; be gentle; be punctual; collect facts—and acknowledge your mistakes.

VETERINARY REPORT ON THE NILE EXPEDITION.

A VERY interesting report by Mr. Fleming, the principal veterinary surgeon, respecting the health of the animals employed in the recent Nile expedition, has just been issued from the War Office. The numerical returns forwarded by the veterinary surgeons unfortunately do not afford the means of compiling a clear statement of the losses of each class, and the injuries and diseases by which these were occasioned. From the report of Mr. Burt, the inspecting veterinary surgeon of the expeditionary force, we learn that the number of camels purchased was about 7050, and that at the end of March, 1885, only 3016 remained, showing a loss of 4034, or upwards of 57 per cent. At the end of December, 1884, when the desert and river columns left Korti to proceed to the relief of Khartoum, the strength of the camels was about 4400, that of the desert column being about 4050, and of the river 350. The former lost in dead, destroyed, killed, and missing 1850, and the latter 32, being respectively in the ratio of 43·6 and 9·1 per cent. In addition to these, 268 died or were destroyed at Korti, and 180 died while out grazing with natives. The loss in the expedition to Metammeh, therefore, between the 30th December and the 25th March amounted to 53 per cent. It is stated that of these numbers 160 were shot or died from wounds received in action, being in the ratio of 3·6 per cent. of the strength. The causes of the great mortality of the camels were chiefly under-feeding, over-work, insufficient supply of water, and the original faulty selection of the animals; it was due, in fact, "to starvation and over-work, and not to disease." As regards feeding, it is stated that on the march from Korti to Gakdul Wells only between three and five pounds of grain were issued. It was hoped that this might be supplemented by grazing, but this was found to be almost impossible under the circumstances. The river column was better off in regard to supplies both of green forage and water. With reference to overwork, Mr. Smith says: "There is no doubt that the strength of the camel was much over-rated and taxed. He was loaded and expected to carry much more weight than should have been the case.....The estimate of weight by the soldiers seemed at times very vague, more often 600 lb. or 700 lb. being loaded than 400 lb." The marches, also, they were required to perform were too long, ranging generally between twenty and thirty miles and occasionally exceeding that distance, while sixteen miles are considered to be a fair day's work; and it was impossible to give them an occasional rest from work. On the subject of watering the camels, Mr. Fleming states that "before the desert column started from Korti an order was issued that the camels were to be watered only every third day, with the object, it is supposed, of accustoming them to exist for long periods without water. This was not very judicious treatment, especially when it was well known that the animals would have little else than dry food on their journey." The order would appear to have been issued without consulting the

responsible head of the veterinary department on the spot. Another important factor in causing the high rate of mortality was the injudicious purchase of animals which were too young to undergo the fatigue of the work they had to perform. Mr. Fleming says: "I am informed that from 25 to 30 per cent. of the camels were scarcely more than two years old; but a camel is not able to undergo hard work until it is six or seven years old." Another cause of disease appears to have been the great variations in temperature to which the animals were exposed, without any adequate covering to protect them from the cold at night, the thermometer ranging between 39° and 92° Fahr. A recommendation for the issue of a strong blanket to each camel was not adopted, owing, it may be presumed, to the difficulties arising from deficent means of transport. The greatest cause of inefficiency was the enormous amount of sore backs, arising partly from the use of badly fitting pack-saddles, and partly from the ignorance or carelessness of the men in charge of the animals. For instance, it is stated that a convoy of Aden camels "marched from Kosseir to Assouan, a journey of sixteen days, during which the saddles were only once taken off." It is but fair to state, however, that in many instances the men were greatly over-worked, as "it sometimes happened that there were five, and often six, animals to one driver." Colonel Furse, the Director of Transport, very justly observes that "the officers and men, after a long and wearisome march, were as fatigued as the camels, and darkness allowed of nothing beyond their bestowing a very superficial attention to injured animals." We have hitherto confined our remarks to the camels, but there is also a very interesting report upon the horses of the 19th Hussars, by Colonel Barrow, the commanding officer. In the eight months from November, 1884, to July, 1885, the losses in a strength of 350 horses were 71, or 20 per cent. Of these, 20 were killed in action, 3 died from wounds, 31 from exhaustion, and 17 from other causes. In the march across the desert, the horses suffered great privations, especially want of water, of which on one occasion they were completely deprived for fifty-five hours. The animals were Arab stallions of an average height of 14 hands, and they carried an average weight of about 14 stone. The comparatively satisfactory results as regards the health of these animals were mainly due to the judicious arrangements made by Colonel Barrow, and the careful supervision which his report shows him to have exercised.

Very much of the untoward results which are recorded in this report was undoubtedly attributable to the inexcusable vacillation and delay on the part of the Government at home, by which the time allowed for the necessary preparations was so limited as to render it impossible to make them in a thoroughly efficient manner. But it was also partly due to the neglect of the military authorities to consult the experienced heads of the veterinary service as to the proper treatment of the camels, and to avail themselves of their skilled opinions in their purchase. Mr. Fleming makes a very fair complaint of the manner in which the officers of the department which he so efficiently conducts were ignored. A letter is appended to the report from Colonel Furse, who was Director of Transport to the expedition, in which he calls in question some of the complaints made by the veterinary officers; but the defence may be summed up in the statement that "they must, as can be seen by their reports, admit that many of the faults they bring to notice had their origin in the very unusual peculiarities of the undertaking." The report contains a large amount of valuable information respecting camels and their value as transport animals, which cannot fail to prove useful when troops are employed in countries where they are available, and the manner in which it has been prepared is very creditable to the officers concerned. We trust that, as suggested by Colonel Furse, a manual for use on future occasions may be drawn up from the data thus collected, so that a recurrence of some of those mischances which marred the character of the Nile expedition may be prevented.

REGISTRATION OF PLUMBERS.—At a meeting of the Plumbers' Company on the 30th ult., it was reported that the movement initiated a short time since by the master and other members of the guild for the improvement of the plumbing trade, with a view of protecting the health of the public, had been attended with much success, and that several hundreds of plumbers had already registered themselves.

THE COLONIAL AND INDIAN EXHIBITION.

[FIRST NOTICE.]

BY an almost unanimous verdict this year's Exhibition has proved the most popular and attractive of all the displays at South Kensington. It presents scenic effects which in themselves suffice to draw immense crowds. Intending emigrants, and those whose friends and relatives already live in the colonies, will naturally find much that interests them personally; while all Englishmen must feel a sense of pride, tempered by responsibility, when they contemplate this magnificent illustration of the vast resources and extent of our colonial empire. Technically, the physician, the sanitarian, the chemist, and the naturalist must see that so vast a collection of the world's products embraces many things that especially concerns him. But it must, nevertheless, be confessed that the sanitary problems involved in the development of British colonisation have not received the amount of attention they deserve. The present Exhibition differs most advantageously from its predecessors by the exclusion of the petty trading elements. On the other hand, commercial interests shown on a larger scale still hold too prominent a position. If England acquires a colony, it should not be solely for the purpose of trade. Care should be taken to show those civilising influences we are capable of introducing, and which are not associated with personal gain. If England assumes the responsibility of governing vast tracts of land, it must be for some other and nobler purpose than that of enriching individual colonists. We should like to see more clearly the improvement our presence has produced on the homes, the material existence, the education and comfort of the native tribes. How far have the resources of civilisation increased the quality and abundance of their food-supply? How far has our superior scientific knowledge contributed to save and prolong the lives of the natives whom we govern by the right of conquest? Our first responsibility is evidently towards those whom we have by force compelled to accept us as their masters. We can only justify domination by improving the lot of those we coerce, and the present Exhibition was an excellent opportunity of showing that, as a race, the English people had understood this high duty. In no respect could we do more than in matters relating to the preservation of public health. We know better than others what are the causes of epidemic and endemic diseases, and we can command the necessary engineering skill to carry out successfully sanitary works. For each colony we should have wished to see in some prominent position a statement showing the improvements effected. The rate of mortality should in all instances be given, and this is only done in some cases. Nor have we yet been able to discover figures that prove the extent of benefit derived from our rule. Surely some of the colonial authorities can state what was the proportion of preventable disease when first English authority was established and what it is now. Nor do we want to know merely the benefit derived by Europeans; but, for conscience' sake, we are more anxious to learn that the lives of the natives have been prolonged by our sanitary works.

There are, of course, some indications of this description to be found at the Exhibition, but it is necessary to hunt them out, and at best they are very incomplete. There is yet a grand work to be done in the vindication of England's honour. This would consist of mortality tables of all our colonies, to demonstrate that, on the whole, English domination has materially contributed to prolong the lives and improve the health of the native populations whose lands our soldiers have conquered, and whose resources our science and commerce have developed.

In respect to therapeutics there is more reason for satisfaction. A very large assortment of medicinal herbs from all parts of the world may be examined. Dr. G. E. Pierez, for instance, exhibits a rich collection of medicinal plants from the West India Islands. The plants are pressed and put in frames, accompanied by a full written description. The following specimen will show the system adopted:—"Colonial name: Christmas Pride. Botanical name: Convolvulus tiliifolius. Natural order: Convolvulaceæ. Uses: This plant is highly extolled by the native midwives, as possessing a powerful emmenagogue action; it is conse-

quently frequently used in tedious labours, an infusion of the root being given."

In the Imperial Court the drugs from East India occupy an ample space. There are about 2000 drugs in India, and of these no less than 1500 were described and shown at the recent Calcutta Exhibition; they have now been brought over to England, though there are scarcely more than 120 that present any real practical interest. It was only right, however, to show all that existed, and the exhibit is the richest of its sort that has ever been seen. The fact that it was prepared by Government has prevented any repetition of specimens; for merchants would have each sent very much the same thing. The purchases of these special samples were made in India by Mr. T. N. Mukharji, acting under the direction of Dr. G. Watt. But the whole of the collections for the Indian Section were gathered together by the Revenue and Agricultural Department of the Government of India, and the primary credit is therefore due to Mr. E. C. Buck, the Secretary to the Government, under whom Dr. Watt acted as chief administrative assistant. Volumes might be, and indeed have been, written on the specimens now placed within such easy access, though some of them, such as the monkshood and wolvesbane, had to be picked from the Himalayan range at an altitude of 10,000 feet. Close upon 800 samples of Peruvian bark, acclimatised in India, are a cheering example of what the Government have done to provide at a cheaper rate this essential febrifuge. The Government plantations at Darjeeling and on the Nilgiris now yield close upon a million pounds' weight of bark. This is for the most part manufactured in febrifuges. Then there are also considerable private plantations in the south of India, and the exports of Indian bark were estimated last year at £100,000.

The opium and hemp cultivations of India are, of course, fully illustrated at the Exhibition, but it is hardly necessary to insist on the obvious importance of these products. The fact that the Indian Government derives an average annual revenue of £9,000,000 from opium alone has, of course, given rise to so many discussions on the advantages and the evils of the opium trade, that it would carry us altogether beyond our province to re-open this vexed question on the present occasion. It suffices, for the moment, to say that, though sanitary questions do not occupy a sufficiently prominent position at the Exhibition, there is, nevertheless, much to be seen that cannot fail to interest the naturalist, the scientist, and the medical practitioner.

NUMERICAL TESTS OF HEALTH CONDITION.

IT is scarcely possible to over-estimate the value of trustworthy mortality statistics, or their beneficial influence upon sanitary progress. The correct construction of mortality statistics and their intelligent interpretation is therefore of the first importance. Very slight examination and study of the subject is sufficient to lead to the conclusion that the crude death-rate—that is, the simple proportion of annual deaths to population—is not a scientifically accurate exponent of the health of the population. Dr. William Farr, in whose hands this imperfect measure of true health or mortality exercised so important an influence upon health progress in England, only claimed that the annual death-rate per 1000 of a population afforded a test of comparative health condition sufficiently approximate for general practical purposes, and he frequently pointed out the limits within which such death-rates could alone be accepted as trustworthy. It is undeniably desirable on many grounds that the disturbing influences which militate against the scientific accuracy of the death-rate, calculated by what has been called the national system, should not be exaggerated. We cannot, in the interest of sanitary progress, surrender the death-rate as an approximate test of sanitary condition until the discovery of a more trustworthy measure of human mortality that may take its place.

During the past ten years the subject of vital statistics has received a continuous accession of students from the constantly increasing numbers of medical officers of health, and there has been a natural tendency upon the part of a certain proportion of those students of vital statistics, including notably Dr. Letheby, Dr. Rumsey, and Dr. Syson, to attach undue importance to the disturbing influences referred to above, and to conclude that the national death-rate system was fallacious and misleading. The subject has been discussed again and again, and it has been conclusively proved not only that the limits of disturbance do not destroy the value of death-rates as a general and approximate test of health condition, but that the principal opponents of the national system based their attacks upon an entire misconception of the inter-relations of birth-rates and death-rates. Except for the fact that this source of error is not yet quite extinct, there would apparently be no excuse for reopening the subject.

Mr. A. Wynter Blyth, in a recently issued Report upon the Sanitary Condition of Marylebone for the year 1885, which is especially valuable for its information bearing upon the influence of tenement life on mortality, deals with the subject of mortality statistics in a manner which calls for special notice. The importance of the subject in its general bearing upon sanitary progress makes it desirable to examine critically some of the statistical statements and suggestions in this report. Mr. Wynter Blyth says: "From want of knowledge of the subject, people are apt to quote mortality statistics as if they were in themselves absolute proof of the health or the reverse of a locality; whereas death-rates, unless interpreted intelligently, are very misleading." He, unfortunately, goes on to assert that "a low death-rate may be caused by a low birth-rate"; and "a high death-rate may be due to a high birth-rate." Here is Dr. Letheby's oft-refuted fallacy revived, with the substitution of *may be* for *is*. It is unquestionably true that the death-rate of a population is appreciably dependent upon its age constitution. A low death-rate may be due to abnormally favourable, and a high death-rate to abnormally unfavourable, age constitution of the population. It is, however, absolutely true that, in all actual populations, a low birth-rate implies an age constitution unfavourable to the death-rate; while a high birth-rate implies an age constitution favourable to the death-rate. If, therefore, it were justifiable to attribute to the birth-rate any influence upon the death-rate, which it is not, it might be said that a low death-rate may be due to a high birth-rate, and a high birth-rate may be due to a low death-rate. It can never be true, however, with regard to actual populations, to say, as Mr. Wynter Blyth says, that a low death-rate may be caused by a low birth-rate, and that a high death-rate may be due to a high birth-rate.

Mr. Wynter Blyth claims to suggest a new numerical test of the sanitary condition of a district. He says: "The mean duration of life, which is computed from both the birth-rate and death-rate and the rate of increase, are, all things considered, a better guide to the state of a district than any other single class of statistics." The value of some new numerical test of sanitary condition which should be more trustworthy than the death-rate, calculated by the national method, could not be well over-estimated, and all suggestions in this direction deserve careful consideration. We are told that if b be taken to represent the birth-rate of one unit of the population, d the death-rate of one unit of the population, r the rate of increase, and x the mean duration of life, then $x = \frac{\lambda b - \lambda d}{\lambda (1+r)}$. We are not told definitely enough what is meant by "rate of increase"; is it increase of the enumerated population, or merely increase by excess of births over deaths? and does it signify "*annual* rate of increase"? In the absence of this information it is useless to discuss the formula, although the bearing of the rate of increase of population upon the difference between the birth- and death-rates, with reference to the mean duration of life, is not at all clear. Further, when we come to test Mr. Blyth's application of his own formula we are faced by several difficulties. The report proposes to give the mean duration of life (calculated by the above-mentioned formula) for the sanitary district of Marylebone, and for each of its component registration subdistricts. This mean duration of life is said to vary from 37·9 in Christchurch, to 64·7 in Cavendish-square. Bearing in mind the variation of class in the populations of these two subdistricts, it may reasonably be expected that their true mean duration of life would vary widely; but seeing that the formula takes no account of the actual age distribution of the population dealt with, which is the most powerful factor in the control of the mortality, and hence of the mean duration of life, it is impossible to feel any confidence in the figures given. No account, moreover, is taken of the effect of migration, as dis-

tinct from the excess of births and deaths, and its effect upon the increase or decrease of population; and in the case of Marylebone and its registration subdistricts, although the excess of births over deaths in the ten years 1871-80 was 13,235, the enumerated population in 1881 was 4344 fewer than at the previous census in 1871. Mr. Blyth shows in his report that the birth-rate and death-rate in St. Mary subdistrict were equal, and it is well known that the population of the subdistrict is declining by migration; it would be interesting to know how Mr. Blyth uses his formula for arriving at the mean duration of life in this subdistrict.

Finally, it conclusively appears from Mr. Blyth's report, that his figures, purporting to give the relative mean duration of life in the several registration subdistricts of his sanitary district are untrustworthy, either because the formula is fallacious, or because it has been incorrectly applied. The term "mean duration of life," scientifically or technically, signifies the mean age at death of a life-table population—that is, of a theoretical population under observation from birth to death, undisturbed by migration, and in which the births are equal to the deaths. In any population in which the births exceed the deaths, or which are affected by migration, the mean age at death differs materially from what is technically known as the mean duration of life. But to return to Mr. Blyth's figures, he calculates the mean duration of life in St. Mary subdistrict as 45·0 and in St. John subdistrict as 43·3 years. Now another table shows the death-rate per 1000 living in 1885, at five groups of ages, in each of these registration subdistricts. From this table it appears that the death-rate in St. Mary subdistrict very considerably exceeds that in St. John subdistrict at each of these five age periods. It follows, therefore, inevitably, that the true mean duration of life must be much lower in St. Mary than in St. John subdistricts, instead of being higher, as it is made out to be when calculated by Mr. Blyth's formula.

The value of the "mean duration of life," if correctly calculated, as a test of health condition, is entirely beyond question; but a life table is the only correct basis for its calculation, and this involves laborious calculation. As regards Mr. Blyth's method for calculating the "mean duration of life," his formula requires further elucidation, but in the meantime the figures said to be computed by it are unquestionably fallacious.

WILLS OF MEDICAL MEN.

THE will and two codicils of Mr. Thomas Pennington, M.R.C.S., L.S.A., formerly of 59, Pembroke-place, but late of 22, Devonshire-road, Liverpool, were proved at the Liverpool District Registry on the 14th ult., by Mr. James Pegram and the Rev. John Smith, the acting executors, the value of the personal estate amounting to upwards of £121,000. The testator after making sundry bequests, including some in favour of local charities, devises all his real and bequeaths the residue of his personal estate upon trust as to the income for his wife, Mrs. Jane Pennington, his sister, Sarah Sleddon, and his three grandchildren John Reginald Richard Pennington, Thomas Robert Pennington, and Edith Sarah Bremner, in equal shares; with remainder in favour of the children of such grandchildren.

The will of Alfred Pett, M.D., late of 57, Avenue-road, Regent's-park, who died on April 3rd last, was proved on the 28th ult. by Mr. James Hilton, one of the executors, the value of the personal estate amounting to over £28,000. The testator bequeaths his watch, chain, diamond ring, and plate to his wife, Mrs. Mercy Pett, for life, and then to his daughter, Louisa Harriet; £200, and his household furniture, books, and the rest of his effects to his wife; an annuity of £300 to his wife so long as she remains his widow, in addition to the provision made for her by their marriage settlement; an annuity of £100 to his daughter, Louisa Harriet, while unmarried; and legacies to his sisters and to his executors. The residue of his real and personal estate he leaves upon trust for his three daughters, Emilia Louisa Bond, Mary Gertrude Pryor, and Louisa Harriet Pett, in equal shares.

The will of Richard Parry, M.D., of 2, Lancaster-terrace, Regent's-park, who died on May 10th last, was proved on the 9th ult. by Mrs. Eliza Ann Parry, the widow, and Mr. Joseph Prosser Hill, the executors, the value of the personal estate amounting to upwards of £12,000. The testator gives the cash at his bankers and his household furniture and effects, except a few articles specifically bequeathed, to his wife; £500 to his daughter, Rosa Menpes; and two or three other legacies. The residue of his real and personal estate he leaves upon trust for his wife for life; then as to £2000 for his son, Thomas Palmer Parry, for life; and the ultimate residue for his three daughters, Mary Harriet Parry, Rosa Menpes, and Jessie Buckle.

The will of Peter Mageniss, M.D., of 27, Euston-road, King's-cross, who died on March 1st last, was proved on the 28th ult., by Mr. John Ortelli and the Venerable Patrick Mageniss, the executors, the value of the personal estate amounting to upwards of £10,000. The testator confirms the settlement of property made by him on his daughter, Catherine Rose, at her marriage; and gives the rest of his estate upon trust for his grandson, Vincent Peter Kennedy.

The will and codicil of Alexander Guthrie, M.D., Deputy Surgeon-General, H.M. Army, formerly of Maisondieu, near Brechin, N.B., but late of Fort Pitt House, Chatham, who died on March 3rd last, were proved on the 29th ult. by Mr. John Guthrie, the brother, Mr. Montagu St. John Maule, and Mr. George Cottrill Downing, the surviving executors, the value of the personal estate amounting to over £8000. The testator bequeaths his household furniture, plate, linen, china, and goods to his wife, Mrs. Emily Guy Menzies Guthrie. As to the residue of his property, he leaves the whole income to his wife for life, but if she marries again one-half only; and subject thereto to be equally divided among his lawful children.

The will of Richard Tuthill Massey, M.D., formerly of Park-road, Redhill, but late of 18, Powis-road, Brighton, who died on Feb. 17th last, was proved on the 22nd ult. by Mrs. Anna Massey, the widow and sole executrix, the value of the personal estate amounting to over £2000. With the exception of a legacy of £900 to his sisters, Mary Anne and Caroline, the only legatee under the will is testator's wife. His daughter Beatrice Jane is fully provided for by his marriage settlement.

The will of James Thompson, M.D., formerly of Avenue House, Leamington, but late of 1, Matheson-road, Kensington, who died on the 5th ult., was proved on the 3rd inst. by Mr. Andrew Thompson, the brother, and Mr. Edward Henry Panton, the executors, the value of the personal estate amounting to nearly £2000. The testator gives a few memorial legacies, and the other legatees under the will are his wife, Mrs. Mary Jane Thompson, and his two daughters, Millicent Phœbe and Kathleen Mary.

The will of Mr. Frederick John Alexander, Surgeon, of Margery Hall, Margery-park-road, Essex, who died on April 7th last, was proved on the 18th ult. by Mr. Horace Augustus Alexander, the brother, and Mr. Frederick Bush, the executors. The testator leaves an annuity to his mother, a legacy to his housekeeper and her husband; and the residue of his real and personal estate upon trust for the benefit of his wife, Mrs. Lucretia Sanders Alexander.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Henry Christey, formerly of Beer-lane, Tower-hill, but late of 23, St. Andrew's-square, Hastings, the gross value of whose personal estate amounts to nearly £14,000, after bequeathing legacies amounting to £350 to his brother and sisters, leaves and bequeaths all the rest of his property to the London Hospital, Whitechapel-road.—Mr. William de Hague, of the East India United Service Club, St. James's-square, and the Langham Hotel, Langham-place, £3000 each to St. George's Hospital, the Middlesex Hospital, the London Hospital, the Royal Hospital for Incurables, West-hill, Putney-heath, the Westminster Hospital, and the City of London Hospital for Diseases of the Chest, City-road.—Sir Henry Morgan Vane, of 74, Belgrave-square, £200 each (free of duty) to St. George's Hospital, Hyde-park Corner, and the General Infirmary, Northampton.

EAST LONDON NURSING SOCIETY.—Princess Christian presided on the 6th inst. over a drawing-room meeting on behalf of this Society, the object of which is to provide nurses for the sick poor, in their own homes, in the east of London. It is now at work in twenty parishes, and employs a similar number of nurses, who are under the supervision of three matrons.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Aylesbury Rural District.—Dr. Hilliard has to record a considerable freedom from mortality by reason of infectious diseases. Aston Clinton has been much benefited by Lady de Rothschild's intervention in laying the mains of the Chiltern Hills water through the village. Some cottages, however, still resort to wells liable to pollution, and the authority should see that this is no longer tolerated. Bye-laws as to buildings have been enacted, and much benefit is expected to result from them. Dr. Hilliard's report includes a careful *résumé* of vital statistics and meteorological records.

Newcastle-upon-Tyne Urban District.—Mr. Henry Armstrong's annual report practically forms a handbook on the health of the city under his sanitary supervision. So far as mortality statistics are concerned, the city has in its general death-rate retrograded; the rate for 1885 being 26·0 per 1000, and standing higher than it has done since 1875. Under the Local Improvement Act 1727 cases of infectious diseases were reported, 1227 being scarlet fever, 253 enteric fever, 93 diphtheria, and 70 small-pox; there were also 9 cases of typhus. Of the latter, it is said that 8 cases occurred in separate houses, and one in an institution. The failure of the disease to spread must largely be attributed to the resort to isolation in hospital. In all, 128 patients were removed to either the fever or the small-pox hospitals, the accommodation in which is at present much restricted. In 1883 a systematic house-to-house inspection of the borough was commenced, a special staff of inspectors being engaged; and the results include a return for every inhabited dwelling in the city, except two, admission to which was refused. The number of defects which came under notice has been great, and a large amount of valuable work has been the result, all this being set out in summary in Mr. Armstrong's report. In addition to the general report, a special one is submitted on the water-supply of the city. It forms an exhaustive summary of all the conditions under which a water-supply should properly be conveyed to a city and its inhabitants, and of the evils and drawbacks to be avoided if a wholesome supply is to be utilised to the utmost advantage.

Batley Urban District.—The general death-rate for 1885 was 19·4 per 1000, and that for zymotic diseases was as high as 3·69 per 1000, the principal causes being whooping-cough, diphtheria, scarlet-fever, and measles. Action was taken to stay the spread of infection, but though the matter has for years past been brought under the notice of the Corporation, Batley still has no means for the isolation of first attacks of infectious diseases. A summary of dangers to health includes references to houses without proper drainage, dwellings fouled by contiguity to middens and privies, need for proper drain disconnexion, inadequate privy accommodation, and houses otherwise unfit for habitation. Reference is made in Dr. Swann's report to Dr. Thorne Thorne's inspection of Batley in 1878; and we fear that, in many respects, the town remains much what it was at that date.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5609 births and 3064 deaths were registered during the week ending July 3rd. The annual death-rate in these towns, which had been equal to 16·8 and 17·0 per 1000 in the preceding two weeks, further rose last week to 17·6. During the thirteen weeks ending on Saturday last the death-rate in these towns averaged only 18·6 per 1000, and was 2·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·3 in Salford, 14·2 in Derby, and 14·7 in Sunderland. The rates in the other towns ranged upwards to 23·3 in Halifax, 25·9 in Plymouth, 26·9 in Manchester, and 30·4 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding three weeks from 263 to 312, further rose last week to 333; they included 115 from measles, 86 from diarrhœa, 67 from whooping-cough, 30 from "fever" (principally enteric), 20 from scarlet fever, 15 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Sunderland, Wolverhampton, or Derby; whereas they caused the highest death-rates in Bolton, Portsmouth, and Preston. The greatest mortality from measles occurred in Oldham, Portsmouth, Bolton, and Preston; from diarrhœa in Plymouth and Blackburn; from whooping-cough in Manchester and Salford; and from "fever" in Newcastle-upon-Tyne, Portsmouth, and Birkenhead. The 15 deaths from diphtheria in the twenty-eight towns included 9 in London, 3 in Liverpool, and 2 in Nottingham. Small-pox caused no death either in London and its outer ring or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had been 31, 23, and 17 on the preceding three Saturdays, had further declined to 14 at the end of last week; 2 cases were admitted to these hospitals during the week, against 2 and 4 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 184 and 194 in the preceding two weeks, further rose last week to 197, but were 23 below the corrected average. The causes of 68, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Nottingham, Brighton, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Oldham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 21·7 and 20·2 per 1000 in the preceding two weeks, rose again to 20·8 in the week ending July 3rd; this rate exceeded by 3·2 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·7 in Aberdeen and 13·1 in Dundee, to 25·9 in Leith and 31·2 in Paisley. The 514 deaths in the eight towns showed an increase of 76 upon the number in the previous week, and included 16 which were referred to diarrhœa, 15 to measles, 10 to scarlet fever, 10 to whooping-cough, 4 to "fever," (typhus, enteric, or simple), 4 to diphtheria, and not one to small-pox; in all, 59 deaths resulted from these principal zymotic diseases, against 49, 57, and 65 in the preceding three weeks. These 59 deaths were equal to an annual rate of 2·0 per 1000, which exceeded by 0·1 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 10, 17, and 20 in the previous three weeks, declined again last week to 15, of which 9 occurred in Leith and 5 in Edinburgh. The 16 deaths attributed to diarrhœal diseases showed a further increase upon the numbers in recent weeks, but agreed with the number in the corresponding week of last year, and included 7 in Glasgow and 4 in Edinburgh. The 10 deaths from whooping-cough showed a marked decline from recent weekly numbers; 8 were recorded in Glasgow. The 10 fatal cases of scarlet fever, on the other hand, showed an increase, and included 9 in Glasgow. Two of the 4 deaths referred to "fever" and to diphtheria were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 93 and 86 in the previous two weeks, further declined last week to 77, but exceeded by 8 the number in the corresponding week of last year. The causes of 72, or more than 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 20·8, 22·9, and 24·7 per 1000 in the preceding three weeks, declined again to 22·9 in the week ending July 3rd. During the thirteen weeks of the last quarter the death-rate in the city averaged 25·6; the mean rate during the same period did not exceed 17·2 in London and 19·7 in Edinburgh. The 155 deaths in Dublin last week showed a decline of 12 from the number in the previous week, and included 12 which were referred to the principal zymotic diseases, against 5, 7, and 10 in the previous three weeks; 4 resulted from "fever," 4 from whooping-cough, 3 from diarrhœa, 1 from scarlet fever, and not one either from small-pox, measles, or diphtheria. These 12 deaths were equal to an

annual rate of 1·8 per 1000, the rates from the same diseases being 1·8 in London and 2·3 in Edinburgh. The fatal cases each of "fever," whooping-cough, and diarrhœa showed an increase upon the numbers in the previous week, and that of scarlet fever a decline of 2. The 28 deaths from "fever" in the thirteen weeks ending last Saturday were but half the number in the first three months of the year. Six inquest cases and 4 deaths from violence were registered; and 55, or more than a third, of the deaths were recorded in public institutions. The deaths of infants showed an increase upon recent weekly numbers, whereas those of elderly persons had declined. The causes of 21, or 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major F. Alfred Turton has retired upon temporary half pay.

ADMIRALTY. — The following appointments have been made:—Surgeon Henry W. D. Walsh, to the Bermuda Hospital; Surgeon Michael J. M'Carthy, to Hong-Kong Hospital; Surgeon Samuel Keays, to Plymouth Hospital; Surgeon T. Dunlop, to the *Icarus;* Surgeon G. C. Ward, to the *Alecto;* Surgeon J. Barry, to the *Banterer;* Surgeon W. G. E. Smith, to the *Flying Fish;* Surgeon Thomas M. Sibbald, to the *Duke of Wellington;* and Surgeon and Agent Charles Harrison, to Castletown, Berehaven.

INFANTRY MILITIA. — 3rd Battalion, the Connaught Rangers: Surgeon George W. Hatchell is granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Duke of Cornwall's Light Infantry: Acting Surgeon John Henry Jenkins resigns his appointment; William Nettle, Gent., to be Acting Surgeon.—1st Volunteer Battalion, the Lincolnshire Regiment: Surgeon and Honorary Surgeon-Major C. B. Moody resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement.—1st Sussex: James Turton, Gent., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

THE APPROPRIATION OF PATIENTS BY CONSULTANTS.

To the Editor of THE LANCET.

SIR,—Will you allow me to bring under your notice what I call the absorbent action of consultants as exerted on patients introduced to them by general practitioners? A few weeks ago I felt specially sore on this point, as within a short period previous to that I had discovered that three patients, whom I had introduced to as many consultants, had been blandly absorbed by these gentlemen as their own exclusive property. It is fair to say that in one of these cases the consultant has since given me a full explanation of the circumstances. This was not my first experience of such treatment, but the accidental occurrence of three cases was the immediate cause of my then soreness. I frequently have heard of similar cases from my neighbours, and there can be no doubt that there is no longer that perfect safety in calling in a consultant that used to exist. This, it seems to me, is a matter much to be regretted, not only because it increases the hardships of our professional existence, but because it indicates a certain loss of tone in the moral fibre, and must, if carried on, finally land us in a death-clutch at each other's throats. No longer shall we be able to trust a brother practitioner to see a patient for us if we are ill; no more shall we find available that outside assistance on which, in cases of emergency, we have been accustomed to rely—in a word, it will be "every man for himself."

In California there is a process called "jumping a claim." Land in the gold districts is there taken up by parties of two, three, or four, and it is no uncommon thing for a small party to awake one fine morning and find a notice on their claim to the effect that a larger party has taken it. On remonstrance, it is customary for the larger party to produce their revolvers, and to remark that, their numbers being four, five, or six, as the case may be, to the original party of three, four, or five, it will be best for the rightful owners to depart.* This is about our position with regard to consultants. We find our patients being assimilated by them, and in view of their moral revolvers—in other words, this titles, their position, and their prestige—we are obliged to recognise the futility of resistance, and resignedly to see our patients "jumped." Whether the struggle for existence in the upper ranks of the profession is the real cause of this behaviour, or whether it is ignorance of the ethical laws which swayed the conduct of our ancestors, the result is the same: there is a loss of tone, and the gentlemanly honour of the profession loses its lustre. Men are too ready to believe what patients say of their doctors. There is no subject on which the laity so unblushingly lie as on that of their relations with their doctors. Does a patient owe a doctor a bill and on that account for very shame hesitate to call him in, he will tell another doctor that his reason for changing is on account of some error of his original doctor. If a consultant asks a patient who comes for a second consultation without his regular adviser the reason of this absence, he is most probably told that the patient and the doctor have quarrelled, whereas the real reason is that the patient thinks to save the double fee. And so it is in many other instances, so that now I, for one, never believe what a patient tells me about doctors.

I have mentioned the "double fee." There is no doubt that this fact, that when a patient is accompanied by his own medical adviser a fee of two guineas is charged when if he went alone he would only have to pay one, goes a long way to account for the action of the patient. As has been frequently observed, this method of procedure is a little difficult to explain, for when the medical or surgical particulars of the case are ready cut and dried there cannot be so much for the consultant to do as when he has to ferret them out for himself. And, sad to tell, by this increase of charge the consultant lays himself more open to be assailed by temptation, as men will always try to get as much as they can for as little as possible. Altogether, Sir, what with absorbent consultants, prescribing chemists, and pay wards at the hospitals, the general practitioner's outlook is not cheerful. Cannot you help us? A few words from you may make the consultants more careful and more willing to observe the good old rule by which one medical man, in times now nearly gone, would absolutely refuse to see a patient to whom he had been introduced by another without the knowledge and consent of that gentleman. After all, this is only another reading of a still more ancient rule which bids us do to others as we would they should do to us.

I am, Sir, yours truly,

Holloway-road, N., July 6th, 1886. W. HENRY KESTEVEN.

THE RECENT CHOLERA SCARE AT QUEENSLAND PORTS.

To the Editor of THE LANCET.

SIR,—As some doubt seems to have been expressed in certain quarters as to the nature of the symptoms, supposed to be those of cholera, which have recently been manifested in the latter part of the outward voyage on certain Queensland Government emigration steamships, and which proved fatal to several of the emigrants on the *Dorunda*, it would be interesting to inquire whether there could be any other cause tending to modify the diagnosis, for it is well known, as Dr. F. Roberts remarks in his "Handbook of the Theory and Practice of Medicine" (3rd ed., p. 226, vol. i.), that "intense gastro-enteritis, excited by poison or some other irritant, has been mistaken for cholera." As I happened to be temporarily filling the post of surgeon to an outward-bound steamer, calling at Queensland ports, which immediately succeeded the *Dorunda* at Batavia at the time of the occurrence—viz., at the close of last year and the commencement of the present,—it may be presumed that the inquiry is not without some personal as well as public interest. The medical officer of health at one of the Queensland ports, who had acquired considerable practical acquaintance with the symptoms of cholera during a residence in Central America of some years, expressed to me very decided doubts as to the accuracy of the diagnosis, though I think I am not now justified in mentioning his name. Hearing by telegram of the fatal sickness which had occurred on the *Dorunda*,

and being warned—too late, however—not to enter the harbour of Batavia, we were not without some anxiety lest we ourselves should suffer in like manner—a fear which appeared not wholly unfounded on the occurrence of several cases of severe colic, of a nature somewhat mysterious in origin, but happily more or less readily yielding to medical treatment, some time after leaving that port.

In a previous letter in your columns (see THE LANCET, April 24th last) your readers may have noticed my mention of what appeared to afford ground for suspicion as to the cause of the symptoms which came under my notice, and which I suggested as probably due to zinc-poisoning, a view which received confirmation on referring to the researches of M. L. l'Hote in *Comptes Rendus*, in the decomposition of water by zinc in the presence of iron, and from the manifest presence of the injurious metal in a sample of the water we had been consuming, which I had reserved and submitted to chemical test after my return home; the possible cause of the epidemic having been first suggested by one of the ship's engineers, who was aware of the presence of zinc anti-corrosive plates affixed inside the boiler we had been using for condensing purposes. Since somewhat similar symptoms, but fortunately not fatal, have more recently occurred on board the Queensland Government emigration steamship *Quetta*, which you have remarked as being in all probability not of a choleraic nature, it would be interesting, from a medical aspect, to inquire whether these ships also have, in like manner, zinc anti-corrosive plates in their condensing boilers, which, supposing the invention of modern application, would excite greater suspicion if the ships in question are of more modern construction than others in the line of service. If so, we arrive at what would seem to be an interesting confirmation of a probable cause of certain symptoms which, even though fatal in several cases on board the *Dorunda*, have at least been adjudged by certain individuals to possess some difference in type and duration as compared with those usually manifest in epidemic cholera. Apart from the enfeebling character of a tropical voyage on the average British unacclimatised constitution, which might be supposed to predispose the system to epidemic and other prejudicial influences, in support of the idea suggested as to the probable cause of the symptoms, which give rise to very considerable anxiety and apprehension in Queensland, and which would seem, in case of recurrence, in danger of seriously impeding commerce, it is well to remember that the symptoms appear to have arisen shortly after leaving Batavia, or even before arriving at that port, in the case of the *Quetta*, or, as it is presumed, after the consumption of condensed water—for it is not now usual, I believe, to take in supplies of that commodity at the port of Batavia,—and, as it appeared to me, amongst a section of the ship's company consuming the water most freely, and where, perhaps, the accommodation was not quite so good, or the diet-table so liberally varied.

Without appearing to prejudice the interests of our shipbuilders, whose marvellous works we so much admire, and who would be the first to desire to remedy any palpable error in construction affecting the health of the passengers or crew, or, by raising an unfounded alarm, to interfere with the freedom of invention or of commerce, it might seem that an official inquiry might be instituted on the lines above suggested with manifest advantage, in order to prevent, if possible, the perpetuation of an injury to the health of the sea-going community, and others who may have to depend upon supplies of condensed sea-water for consumption from time to time; and should confirmation be given to a supposed assignable cause of symptoms of illness giving rise to alarm, it is manifest that the inquiry will not be futile. Should, however, there appear to be insufficient ground for an official inquiry on the subject, I should feel glad to receive any information as to the presence of zinc plates in the condensing boilers of the ships in question, or bearing on the subject generally. Whilst in pursuit of the medical investigation, any information tendered by those members of the profession who may have had the charge of the ships where the illness has occurred or of the Brisbane Quarantine Station, or who have had to do with the inspection of the ships of the line where illness has occurred, in their official capacity as port sanitary officers, communicated to your columns, will, I doubt not, be of interest to many of your readers.—I am, sir, yours faithfully,

JOHN WARD, M.D., ex-M.O.H.

Sutton Coldfield, Birmingham, June 15th, 1886.

JOHN HUNTER.

To the Editor of THE LANCET.

SIR,—I beg leave, through you, to tender warm thanks to Mr. Charles Hawkins for having just published in your columns a very remarkable letter from John Hunter to the governors of St. George's Hospital. The great surgeon's writings often leave much to be desired. He was a deep thinker and an untiring worker, but neither a wide reader nor a facile exponent of thought. On the latter point judgment must be expressed with reserve, because facts fail through the deplorable destruction of much of John Hunter's manuscript by Everard Home. That the loss was irreparable is beyond doubt, but whether the papers burnt were rough notes or finished essays it is impossible to say. The letter which you now publish was written some months after John Hunter's last communication to the Royal Society, and not many weeks before his death. It is rich in evidence of philosophic spirit, of enthusiasm for professional work, and of public disinterestedness. Mr. Hawkins tells us that the letter is one of a series in his possession, and that he *may* print the whole correspondence. By doing so I venture, through you, to assure Mr. Hawkins that he will be rendering a very great service to all students of surgical history. As the editor of Sir Benjamin Brodie's writings, and, as one of the comparatively few surviving links between the epoch immediately succeeding the Hunterian and our own times, Mr. Charles Hawkins must possess a store of information which would be priceless now, and irrecoverable unless he place it on public record.

I seize this opportunity for referring to one item in Hunterian history on which information is much needed. John Hunter's wife, sister of Sir Everard Home, bore him four children, of whom two died young; the other two, Agnes and John, were said to be living in 1835, when Henry Ottley wrote the life of Hunter prefixed to Palmer's edition of his works. The Annual Register for 1793, the year of John Hunter's death, states that he left a son in his twentieth year, then at Cambridge. That son, according to information kindly supplied to me by Dr. William Hunter of Rothesay, entered the army, rose to the rank of colonel, and left a daughter, named after his sister Agnes. But I can obtain no further reliable information. Anyone able to supply it will, I am sure, be welcome to your columns.

I am, Sir, your obedient servant,

Birmingham, July 4th, 1886. SAMPSON GAMGEE.

A MISTAKE, A DEDUCTION, AND A MORAL.

To the Editor of THE LANCET.

SIR,—The general brevity of our English summer renders us very liable to forget the fact that in weather such as we are now experiencing the extreme heat of the sun's rays may, without the exercise of due care, be very powerful of harm. A brief mention of the following case will illustrate my meaning, and may not merely be of interest, but, should the weather continue, may also be beneficial in helping others to form at once a correct diagnosis, where I must confess I at first decidedly failed.

On Sunday evening, July 4th, I was called to see Alfred L——, aged four years, a well-nourished, healthy-looking child. His parents, who were very anxious about him, told me he was taken ill on Friday, July 2nd, until which day he had been in his usual health. The only history I obtained of the illness was that he was very restless on Friday evening, shivered slightly, and then became feverish, thirsty, and complained of his throat. I found him lying on his side with his face away from the window, and nearly buried in the pillow. The thermometer registered his temperature at 104° F. His skin was very hot and dry, tongue coated with a white fur, pupils dilated, breathing rapid, and alæ nasi working.

Remembering the prevalence of east and north-east winds, I thought I had to deal with a case of pneumonia or capillary bronchitis. And here comes the harm of forming an opinion before examination. The percussion note was apparently good and breathing vesicular. But I was prejudiced, and at times I thought I detected slight roughness in the breathing on one side, while I fancied the puerile breathing was almost bronchial over one back. However, the signs

were very negative, so I ordered a simple mixture of citrate of potash and spirits of ammonia, with milk diet, and left, promising to return in the morning, when I thought, were I right, the physical signs would have more fully developed. However, I am glad to say that on the same evening, a few hours later, it suddenly occurred to me that the case was one of sunstroke; and then I remembered, again, the position of the child, the dilated pupil, and the avoidance of light; I recalled also a sign of great significance that I have not mentioned before—viz., well-marked reflex muscular irritability, especially in the spinal region; and I put these with the high temperature and absence of lung signs, and was certain my sudden conviction was correct. It was more fully confirmed next day, when the child was much better, the temperature being 100°, lung sounds quite healthy, and muscular irritability much less. He continued the medicine, with a powder of rhubarb and mercury with chalk at bedtime, and also cold to the spine. To-day (Tuesday) he is still more improved and wishes to get up. I have no doubt of his speedy convalescence.

While apologising, if necessary, for the length at which I write, I would urge this deduction. We in England are even more liable to sunstroke in this short summer of ours than they who reside in the tropics. And for this reason: In the tropics the residents are continually alive to the dread effects of the blazing sun, and go about in pith helmets and spinal protectors. In England, we make no change in our dress, treating an almost tropical sun with careless indifference. I suppose this is because our climate is so uncertain. The all-powerful sun of to-day may be hidden by clouds and cooled by rain to-morrow, to shine no more in its potency for another year. However this may be, during this brief season of heat, I would urge a constant and mindful care, particularly extended to children too young to know or care for the danger themselves. And the moral is one I take to heart myself: "Avoid drawing conclusions until certain of the premisses on which they should be based."

I am Sir, your obedient servant,

FRANK STURGES, L.R.C.P., Lond.,
Late Surgeon P. & O. S.S. Co.

Beckenham, July 6th, 1886.

LIVERPOOL.

(From our own Correspondent.)

THE CONVALESCENT HOSPITAL AT WOOLTON.

THE twelfth annual meeting of the supporters of the Woolton Convalescent Hospital was held on June 26th. In this city, as elsewhere, an institution of this kind supplies a great want. Our four general hospitals are not more than sufficient for a centre containing a population of nearly 600,000. Moreover, they are not merely city but county institutions, receiving patients from a considerable distance. It follows therefore that many patients leave our hospitals in a condition which would be greatly improved by a short residence in a convalescent hospital. Woolton is a pleasant village several miles south-east of Liverpool, and the institution is most ably administered. Mr. George Cope has presented £500 for the endowment of a bed to be known as the "George and Thomas Cope bed," for the use of the working people employed in their factory.

THE LOWEST MORTALITY EVER KNOWN.

At the last meeting of the Health Committee, the chairman, Mr. J. B. Smith, remarked that the rate of mortality (18·2 per 1000) was the lowest he had ever known.

THE DEAD-HOUSE.

There would appear to be a special Providence over the wealthier classes of this city. It has never happened that the body of a "merchant prince" has been found floating in the river, been recovered by some waterman, and conveyed to the Prince's Dock Dead-house. Had such an event occurred there would probably have been a general chorus of indignation that the body of any gentleman should have been conveyed to such a miserable place as the mortuary or dead-house has always been. Some years ago it was removed from its former site to another not far off, and it was fully expected that the present structure was only a temporary one. But as years have rolled on this has turned out to be a pleasing illusion. The place as it is, especially in hot weather, is a disgrace to everyone responsible for its continuance. It is, unfortunately, another melancholy instance of what is everybody's business being nobody's business. A very small expenditure would suffice to produce a structure which would be suitable for the reception of bodies, and at the same time not prejudicial to the health of those who have to visit it, and even spend some time there. It is greatly to be hoped that this will soon be done, as otherwise it is quite impossible to say how soon a very serious scandal may arise.

HOSPITAL SATURDAY.

The amount found in the Hospital Saturday boxes exceeds £3000, which is the largest sum received since the first starting of the fund in 1871. It is expected, however, that as years pass on this amount will be considerably augmented, and there can be no reason why the working men of Liverpool should not raise as much as has been done by their fellow-workmen in Birmingham and Glasgow—viz., £5000.

TESTIMONIAL TO DR. HYLA GREVES.

Dr. Hyla Greves was presented on June 29th with a silver bowl as centre-piece and an illuminated address from a number of his medical friends. The presentation took place at a supper at the Adelphi Hotel. Mr. Mitchell Banks presided, and there were about seventy gentlemen present. Dr. Hyla Greves leaves Liverpool for Bournemouth with the heartiest good wishes for his health and prosperity of a very large number of both professional and lay friends; it may, indeed, be said that he does not leave an enemy behind. In the various appointments he has held of physician to the Infirmary for Children and the Bluecoat Hospital, he has won golden opinions, and the regret felt at losing his future services is felt by the committees of both these charities. Dr. Greves has also held office at the School of Medicine as Demonstrator of Anatomy and Medical Tutor, where he was most popular with all the students. His perfect recovery to health after a most serious illness caused the greatest satisfaction to all his numerous friends.

Liverpool, June 30th.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

FRIDAY last was the annual prize day and meeting for presentation of associates of the College. There was a large attendance, and, either owing to the General Election taking place on the same day or to some other cause, the students indulged much more than has been usual of late in giving vent to their animal spirits by the shouting and cheering of names of politicians &c., those of Sir H. Roscoe and Lord R. Churchill being apparently in greatest favour. The report of Dr. Greenwood stated that the number of students during the past session had been 1251, exclusive of those in the department for women. The lady students numbered 66. The number of associates admitted this year was 33, 17 of these being graduates of Victoria University, and 14 either of London, Oxford, or Cambridge. One-half were graduates in medicine, and the remainder in arts or science. In alluding to the resignation of Sir H. Roscoe as Professor of Chemistry, the Principal paid a well-deserved tribute to the part he had taken in bringing the College to its present position, and especially that to him was due the perfection of its chemical laboratories and teaching. An important feature of the year's work is the projected establishment in the immediate future of a hall of residence, to be called the Hulme Hall, already endowed with £1000 per annum.

ELECTION OF SIR H. ROSCOE.

The candidature of Sir Henry Roscoe for the representation of South Manchester in Parliament has again been successful. At the last election Dr. Royle opposed him, but this time Colonel Fowler was the Conservative candidate, and Sir Henry's majority was reduced to some 300 only. No medical man has this time appeared as an aspirant for parliamentary honours in either Manchester or Salford.

MR. LUND.

The heading of the poll by Mr. Lund at the late election for members of the Council of the College of Surgeons has given much satisfaction here, and shows that the time and attention he has devoted to his duties there during the past

eight years have been appreciated. Although resident two hundred miles from London, his attendance at the meetings has been most regular, and demonstrates that efficiency is no monopoly of the metropolitan members.

WORKHOUSE DIETARIES.

Apropos of some correspondence in THE LANCET of the 3rd inst. upon uniformity in workhouse dietaries, it may be mentioned that at a meeting of Poor-law authorities held in the Manchester Town Hall to make preliminary arrangements respecting their autumnal conference, this subject was referred to, and it was determined that it should form one of the subjects for discussion there. Dr. Rhodes, a member of the Chorlton Board of Guardians, has devoted much time and attention to this matter, and he was requested to prepare a paper and introduce the subject at the coming meeting. Another matter also fixed upon for debate was "the abuse of lying-in wards and lock wards in workhouse infirmaries."

THE COMING MAYOR.

It is expected that the office of mayor during the ensuing municipal year will be accepted by the present chairman of the Health Committee, Mr. Alderman Schofield. Under his able direction for some years past sanitary work has been vigorously carried on, and although Manchester is as yet far removed from Dr. Richardson's ideal city, still much has been accomplished in setting our house in order from a sanitary point of view. Perhaps one of the most pressing evils of the present time is the smoke nuisance; that, and the improvement of the homes of the poor, may well occupy the serious attention of the council.

THE ROYAL INFIRMARY.

A vacancy in the post of sister-superintendent of nurses at the Royal Infirmary has been caused by the resignation of Miss McKie, who has held that office for some half-dozen years, and under whose *régime* many and important changes have come to pass in the organisation and accommodation for the nurses and sisters. Although the lady is severing her connexion with the infirmary, she will still retain her interest in the institution, as the occasion of her leaving is due to a matrimonial engagement with one of the junior members of the honorary staff. She will leave with many good wishes for her future happiness. Miss Brown, of St. Bartholomew's Hospital, has been appointed her successor.

Some little speculation is already abroad as to who shall represent the Victoria University in the Medical Council under the provisions of the new Medical Act, but it is too soon at present to mention with certainty any names in connexion therewith.

After much asking, the School Board has at last resolved to allow some of the playgrounds to remain open during the evening for the use of all the children living in the crowded districts in which they are situate, irrespective of whether they attend the schools or not. This utilisation of playgrounds and such spaces as we have for children's recreation is much to be commended.

Manchester, July 5th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

PRESENTATION TO DR. G. Y. HEATH, OF NEWCASTLE.

AN interesting meeting took place last Friday in the library of our infirmary, when a congratulatory address was presented to the much-respected lecturer on surgery by his past and present students, who felt the honour which the worthy Doctor has lately received in being admitted by selection to the honorary Fellowship of the Royal College of Surgeons of England to be an appropriate occasion to express the respect in which he is held here in the north. It is very gratifying that the movement originated and was carried out by students, although Dr. Heath's colleagues and many of his professional brethren were also present, and participated in the expressions of esteem which were rendered at the meeting. Dr. Arnison occupied the chair, and the address presented was inscribed in a handsome album, having special views of the Medical School, the University of Durham, the Cathedral, &c. Dr. Heath replied in feeling terms, and stated that he was quite taken by surprise when the presentation was first mooted to him, and that the honour he had received from the College of Surgeons was quite unsolicited on his part. On the conclusion of the meeting the students gave further expression of their feelings in the familiar but hearty form known as "musical honours."

THE LATE REV. CANON EAST, OF NEWCASTLE.

I much regret to notice the death of this estimable clergyman, who died at St. Andrew's Vicarage, Newcastle, last week, in his seventieth year. Although in holy orders, Canon East was intimately connected with our profession, having originally studied and qualified as a surgeon, and, indeed, practised in London, Coventry, and Leicester. He was a man of wide reading and culture, with marked literary tastes, so that he gradually forsook the medical profession, and became connected with the editorial staff of the *Atlas* and other metropolitan newspapers. Finally he directed his attention to theology, and his superior education secured ordination one year sooner than is usual with candidates for holy orders. He came to Newcastle as a curate of St. Nicholas, but in a very short time he received the living of St. Andrews, where he remained for the rest of his life. He was also chaplain to the garrison in this city. Canon East's sympathy with our profession was of the warmest nature, and his early connexion with it enabled him to take a broad and useful view of many questions concerning our medical charities and their administration.

NEWCASTLE CATHEDRAL NURSE AND LOAN SOCIETY.

The annual meeting of this excellent Society was held last week, when it was stated that owing to the liberal response of the public to the appeal for funds, it was enabled to increase the staff of nurses so as to undertake the whole nursing of the sick poor of the city and district where required; but at the present time, it is stated, there are no poor persons in Newcastle suffering from non-infectious disease who has not received the benefit of skilled nursing by the nurses of the Society. The vast extent of this work will be perceived by the following figures within the past twelve months: 1331 cases have been attended, 13,734 visits paid, and 67 night nurses provided, all thoroughly trained. From the invalid kitchen have been given out 5319 pints of milk, 1354 pints of beef tea, 1451 dinners of meat, rabbit, and fish, 154 puddings, also eggs, cocoa, and other drinks. In September last the committee deemed it well to begin to make a small charge for the nourishment given; since that time £16 17*s.* 10*d.* has been repaid by the pence of the patients to the funds of the kitchen. Notwithstanding the bad times, and the very destitute state of most of the sick, some patients have raised by collecting-cards the sum of £6 4*s.* 8*d.*, and promise to do more in better times. At the conclusion of the meeting, Dr. Beatley stated that of 1331 cases attended by the nurses, over 400 had been patients of the Newcastle Dispensary.

FATAL GUNPOWDER EXPLOSION.

I have sometimes referred in these letters to the reckless manner with which gunpowder is handled and stored by miners and their families. An inquest was held at Lumley, in the county of Durham, on the body of a woman, the wife of a miner. It appeared that the deceased was smoking in a room where there were 6 lb. of blasting powder, when an explosion took place and she sustained fatal injuries. It was shown that the powder cask was uncovered, and it is supposed that she had lit a match and let it fall on the powder.

Newcastle-on-Tyne, July 5th.

THE LATE MR. W. WHITE COOPER.—The London *Gazette* announces that "the Queen has been graciously pleased to ordain and declare that Mary Elizabeth Cooper, widow of William White Cooper, Esq., Fellow of the Royal College of Surgeons, Her Majesty's Surgeon-Oculist in Ordinary, deceased, shall henceforth have, hold, and enjoy the style, title, place, and precedence of a widow of a Knight Bachelor of these realms, in as full and ample a manner as she would have enjoyed the same had her husband survived and received the dignity of a Knight Bachelor; and to command that the said Royal Order and declaration be registered in Her Majesty's College of Arms."

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY MUSEUMS AND LABORATORIES.

For the last five years, during which period the new University medical buildings have been gradually rendered suitable for the occupation of the several departments of medical training, there has been a great growth in the facilities afforded for students and practitioners who desire to take part in original investigations. In every branch of medicine this is the case. In the Anatomy department the present session signalises the virtual completion of the magnificent collections of Goodsir and Sir W. Turner, which are now arranged in a palatial hall open daily for the use of students. Between each of the glass cases in which these historical specimens are preserved a table and chairs have been provided for the use of those studying, so that they may arrange their books and papers, and be able to work comfortably in any part of the building that may be allotted to specimens illustrating the special subjects upon which they are engaged. In the ample space now at command many treasures are brought to light, and fully available for purposes of study, which were formerly all but lost to view in the midst of the copious and crowded collections of the old University museum. In other departments the increase of space has worked no less satisfactorily in securing greatly increased opportunities for study. In the department of Chemistry, Professor Crum Brown presides over a laboratory replete in its arrangements for pursuing investigations in all branches of that science; the same may be said of the departments of Physiology, Pathology, and Materia Medica. In all these departments original investigations by graduates of the University have been carried on for some years; and it is satisfactory to note that in the important branch of Public Health the same result has now, through the unwearied efforts of Sir Douglas Maclagan, been completely attained; for provision is now made for instructing a large number of medical practitioners and students in the science and practice of hygiene, in connexion with which the University grants the degree of B.Sc. (Public Health department). In this department also a complete bacteriological section is now established, although this branch has been for some years pursued in laboratories set apart for the purpose in the departments of Surgery, Medicine, and Pathology. With the completion of the Public Health laboratories this session the University may be said to have arrived at maturity of development in its relation to the advancement of experimental science; and the large number of papers now issuing from its various departments indicate that the facilities it affords are not only appreciated, but increasingly exercised.

ROYAL SOCIETY OF EDINBURGH.

At the last meeting of this Society an interesting addition was made to the long-standing discussion upon the formation of coral reefs. Dr. Guppy, the medical officer in charge of H.M.S. *Lark*, has utilised his three years' sojourn in the vicinity of the Solomon Islands by making a series of observations upon the growth of coral in a variety of external conditions. The point of chief importance in his paper was one which bears intimately upon past and present theories of coral-island formation. From recent soundings in the Pacific Ocean, and a comparison of their results with observations made in the same oceanic area nearly a hundred years ago, Dr. Guppy arrives at the conclusion that coral reefs do not rise to a greater height than from eight to ten feet from the surface, where they are exposed to the full sweep of the trade winds and the accompanying currents; and that in the Straits, where they are protected from these agents, they rise only to within four or five feet of the surface. He therefore concludes that these reefs never rise actually to the surface without the aid of terrestrial upheaval. During his research, Dr. Guppy collected between seventy and eighty varieties of coral, which he transmitted to London, amongst which the specialist at the British Museum has found between thirty and forty as yet undescribed species.

A CORRECTION.

In my report of Dr. Hunter's paper upon the "Duration of the Life of Red Blood-corpuscles," communicated to the Edinburgh Royal Society a fortnight ago, a grave error concerning his method of investigation was inadvertently committed. In the last issue of THE LANCET Dr. Hunter has indicated and corrected this misconception, and as it is a point of considerable importance, I must refer those interested in his method and its results to his lucid letter on the subject.

Edinburgh, July 6th.

PARIS.

(From our own Correspondent.)

PROFESSOR GRANCHER ON PASTEUR'S INOCULATIONS.

At the Hygienic Exhibition which is being held in Paris popular lectures are delivered on the various subjects appertaining to public and private sanitation. Professor Grancher who is one of the lecturers on the list, chose for his discourse the divers phases followed by M. Pasteur in his anti-rabic researches, commencing with the day on which he made his communication to the Academy of Sciences (Jan. 24th, 1881) on the saliva of a child who died of rabies in the ward of M. Lannelongue, up to the time of the application of the experimental methods to young Meister which had hitherto so well succeeded in animals. M. Grancher particularly drew the attention of his audience to the objections that have been raised in different quarters to the method. These objections may, he said, be reduced to two principal classes, one of which is that the substance employed by M. Pasteur in his inoculations does not contain any rabic virus; the other, that the greater number of those that had been inoculated had been bitten by dogs that were not rabid. As regards the first objection, the English Commission that came over to Paris a short time ago to study the method returned fully satisfied that the product used by M. Pasteur in his inoculations really contained the rabic virus. As regards the second objection, M. Grancher made the following remarks: Of 1335 persons who were inoculated to June 21st—that is, the day on which he delivered his lecture—he found that of 96 patients who belonged to the first or experimental category—namely, of those in whom the existence of rabies was indisputable—there was only one death, or a mortality of 1·04 per 100, or, in round numbers, 10 per 1000; and of 644 persons of the second or clinical category, 3 succumbed to rabies, or 0·46 per 100 of the mortality, or 5 per 1000 in round numbers. In comparing these statistics with those of the department of the Seine, it will be seen that the average mortality from hydrophobia has been reduced from 160 per 1000 to 7·5 per 1000. These figures apply only to those bitten by mad dogs. As regards the 48 persons bitten by mad wolves before the 22nd of April, there were 4 deaths; but a calculation based upon eight documents communicated to M. Pasteur indicates a mortality of 82 per 100 after the bites of mad wolves. A paper published by Professor Brouardel in the "Dictionnaire Encyclopédique des Sciences Médicales" on rabies gives a mortality proportion of 67 per 100. Thus it may be seen that the difference between the two results is considerable. To give further proof of the value of the anti-rabic inoculations, M. Grancher compared the efficacy of the three different kinds of inoculations that are now generally practised—namely, that of Jenner, that for charbon, and that for hydrophobia. Before the Jennerian vaccination, the non-vaccinated died from small-pox in the proportion of 500 per 1000, those imperfectly vaccinated succumbed in the proportion of 260 per 1000, and those properly vaccinated in the proportion of 23 per 1000. The preservative action of the Jennerian vaccine is therefore represented by the absolute value of 500:23—that is to say, 21·70. Besides, veterinarians numbering more than 200 who employ the charbonous vaccine give the following statistics:—Mortality before vaccination, 120 per 1000; mortality after, 5 per 1000 on an average. The preservative action of the charbonous vaccine is therefore represented by the absolute value of 120:5—that is to say, 24. Finally, the statistics furnished by M. Leblanc to the Council of Hygiene, compared with those of M. Pasteur, concerning hydrophobia, give the following results:—Mortality before the rabic vaccination, 160 per 1000; after vaccination, 7 per 1000. The preservative action of the rabic vaccine is therefore represented by the absolute value of 160:71—that is to say, 21·85. Thus it may be seen that the three vaccines appear to be sensibly equal, and this surely ought to be sufficiently convincing to

anti-vaccinationists. Notwithstanding such convincing proofs, a good deal of scepticism prevails, and will still prevail for some time, as regards the efficacy of the anti-rabic inoculations as practised by M. Pasteur, and nowhere perhaps has this scepticism been more evident than at the Municipal Council of Paris. While M. Pasteur is receiving liberal subscriptions from all quarters, both at home and abroad, the attitude of the Paris Municipal Council is anything but encouraging to M. Pasteur, as at a recent meeting it voted a donation of only £1000, instead of £2000 as originally proposed, for his institute, and it gave him only a ninety years' grant of half the ground he wanted as a site for it. Meanwhile, awaiting the projected building, the laboratory of M. Pasteur has been transferred to the Rue Vauquelin, the premises in the Rue d'Ulm being far too small to accommodate the influx of patients from all parts.

DEATH OF DR. J. M. PRAT.

Dr. J. M. Prat, a well-known aurist and laryngologist, died at his residence in Paris on June 27th, in the sixty-fifth year of his age, after a long and painful malady. He was the son of a physician, and he devoted himself early to the study of natural and biological science, and was for a long time assistant to Gratiolet at the Museum of Natural History. He took his degree in 1848, and was a member of nearly all the scientific societies of Paris. He was much sought in Parisian society for his accomplishments. He was the author of several works on diseases of the ear and on deafness, and contributed largely to the medical periodicals on the same subject. During the war he was attached to an ambulance, and for his services there he was created Chevalier of the Legion of Honour.

DEATH OF A LADY DOCTOR.

Mdlle. Ribard, M.D., of Paris, who accompanied Paul Bert on his appointment as Resident-General at Tonquin, died from dysentery, very much regretted. The deceased lady promised to become remarkably efficient in her profession. She devoted herself specially to diseases of the eye, and had already been successful in curing several mandarins at Hué, and, had she lived, she would have operated on the Dowager-Queen, who was completely blind.

Paris, July 5th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council of the College held on Thursday last, at which all the members were present, the minutes of the extraordinary meeting of June 24th were read and confirmed. Mr. Marshall presented his report as representative of the College on the General Medical Council. This was received and entered in the minutes, and the best thanks of the Council accorded him.

Mr. W. S. Savory was re-elected President by a large majority. Mr. J. Hutchinson and Sir Joseph Lister were elected Vice-Presidents for the coming year. We have referred in another column to the departure from the usual course in regard to the re-election of the President. The appointment of two new Vice-Presidents is also a variation from the ordinary routine.

The following motion, proposed by Mr. Macnamara, was carried:—"That, in pursuance of the resolution of the Council of the 9th of April, 1885, the Committee on the Mode of Election to the Council, and on other matters relating to the Charters and Bye-laws of the College, be requested to report, with as little delay as possible, on the steps taken by them in reference to the preparation of the new sections required in the charters and the formulæ for new bye-laws to give effect to the resolutions of the Council respecting them."

THE VOLUNTEER MEDICAL STAFF CORPS.—The officers and men of this corps gave their first ball at Kensington Town Hall on July 2nd. A number of distinguished patronesses, including the Princess Louise, lent their names and active assistance to further the interests of the corps, which is expected to benefit financially to a considerable extent by the festivity. The corps is to be congratulated on this the first venture, the more especially as it is intended that the ball should be held annually.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on the 1st inst., the degree of M.B. was conferred on—

Henry Willingham Gell, Balliol; Edmund Taylor Milner, Merton; Henry John Tylden, Exeter; Henry Patrick Cholmeley, Magdalen; Albert W. Webb, non-collegiate.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week by the Earl of Rosse, Chancellor of the University:—

BACHELOR IN SURGERY.—Edward Arthur Crampton Baylor, William Jones Crofton, M. J. Eustace, John Christopher Ferguson, Kenneth Frazer, William Vere MacMahon, John Murray, William Napper, Nevill, Samuel Simpson, Richard Henry Smith, Robert Henry Todd (stip. cond.), George Augustus Wade (stip. cond.), Hugh Woods.

LICENTIATE IN SURGERY.—John O'Connor.

BACHELOR IN MEDICINE.—George Hindes Bagot, Edward Arthur Crampton Baylor, Edward Carrigan, William Jones Crofton, William L'Estrange Eames, Marcus J. Eustace, John Christopher Ferguson, Kenneth Frazer, John Wm. Golden, John Murray, William Napper Nevill, Samuel Simpson, Richard Henry Smith, Brooking Soady, Robert H. Todd (stip. cond.), George Augustus Wade, Hugh Woods.

LICENTIATE IN MEDICINE.—John O'Connor, Perceval Cecil Ryan.

DOCTOR IN MEDICINE.—W. Beatty, Geo Cowen, Benjamin Devonsher Dickson, John Samuel Fenton, Kenneth Frazer, Robert Henry Todd.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 1st inst.:—

Gregory, Alfred John, Clifton-road, St. John's.
Mackonochie, William, Traverse-street, Parr, St. Helen's.
Stabb, Ewen Carthew, Vincent-square, Westminster.

UNIVERSITY OF LONDON ELECTION.—The poll for a Parliamentary representative closed on Thursday at 4 P.M., with the following result:—Sir John Lubbock, 1314; Mr. Frederic Harrison, 516. The votes of the medical graduates were distributed as follows: for Sir John Lubbock, 495; for Mr. Harrison, 43.

A DENTAL HOSPITAL for Brighton was opened on the 1st inst.

ACTORS' BENEVOLENT SUNDAY FUND.—Mr. Henry Irving has forwarded to the Lord Mayor the sum of £111 1s. 9d., being remitted to him collected in the boxes at the London theatres the amount collected for the Sunday Fund.

MEDICAL MAGISTRATE.—The Lord Chancellor has, on the recommendation of Earl Sydney, Lord-Lieutenant of the County, appointed Richard Rothwell Daglish, M.R.C.S. &c., to be a Commissioner of the Peace for the borough of New Romney, to the county of Kent.

FIRE AT THE BRUSSELS UNIVERSITY.—A destructive fire occurred on the 7th inst. at the Brussels University, when the whole of the right wing, where the laboratories, the library, and the great academic hall were situated, was entirely destroyed in less than an hour, though some of the books in the library were saved by the students. The collections of anatomical specimens and surgical instruments and the whole of the left wing escaped destruction. The damage is estimated at one million francs, none of which is covered by insurance.

GUY'S HOSPITAL.—The annual distribution of prizes to the successful students attending Guy's Hospital Medical School took place on the 1st inst. in the presence of a large assembly. The following is a list of the principal prize-winners:—The Treasurer's gold medal for Clinical Medicine, John Wychenford Washbourn; the Treasurer's gold medal for Clinical Surgery, Frédéric François Burghard; the Frédéric Clinical Study (£25), Richard Gurney Hoare prize for Clinical Surgery (£31 10s.), Moody-Ward; the Beaney prize for Pathology (£31 10s.), John Wychenford Washbourn; the Mackenzie Bacon prize for Ophthalmoscopy (£10 10s.), Sidney Wacher; the Mackenzie Bacon prize for Nervous Diseases (£15), Edward Cooper Perfect prize for Hygiene (£10), Wilberforce Goodall; the Burdett Coutts Cox Scholarship (£15 for three years), Alfred Parkin; Sandwith prize (£10), divided between Alfred Parkin and Robert William Henry Bowes; the Michael Harris prize for Anatomy (£10), divided between the Fifth Year's Students, Frédéric Devereux Mothersole. For Forensic Medicine (£25), and Francis Stanhope Hawkins, second prize (£10); the Royal prize (£25), and Ernest Henry François Burghard, first prize of £10 for Third Year's Students, Arthur Edward Poolman, first prize; Colle Starling, second prize (£10).

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following sums, collected in the places of worship mentioned, as well as gifts from individual donors, have been forwarded to the Mansion House since our last issue. The amounts raised in 1885 for the same object are also given for the purpose of comparison, which it will be seen is, with very few exceptions, highly favourable to this year's returns.

* Moiety. † Proportion. ‡ Two-thirds offertory.

The total sum received up to Thursday evening last amounts to £31,300 (quite £500 more than on the corresponding day last year).

ERRATUM.—In our list of collections published last week, page 60, line 1, for "Merton Park Church," &c., read Merton *Parish* Church.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

CHARLTON, CLIFTON, M.B., C.M.Ed., has been appointed Assistant-House-Surgeon to the Liverpool Northern Hospital, vice Fisher, promoted.

CLARKE, J. MICHELE, M.A., M.B.Cantab., has been appointed Assistant Physician to the Bristol General Hospital.

FISHER, ALFRED, M.R.C.S., L.R.C.P.Ed., has been appointed Senior House-Surgeon to the Northern Hospital, Liverpool, vice Johnston, resigned.

GRIFFIN, JOHN, M.B., C.M., has been appointed Assistant Physician to the Royal South Hants Infirmary.

HENDERSON, G., M.R.C.S., has been appointed Medical Officer for the Carham District of the Glendale Union.

HERN, JOHN, M.D.Edin., M.R.C.S., has been appointed Ophthalmic Surgeon to the Darlington Hospital.

HOWE, J. DUNCAN, M.R.C.S., L.S.A., has been appointed Resident Medical Officer to the Manchester Workhouse Infirmary.

LIDDARD, THOMAS, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer to the Workhouse, Mary-place, of the Parish of St. Mary Abbotts, Kensington.

LOWNDS, HENRY A., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Kirkbinton District of the Huddersfield Union.

OSWALD, ROBERT J. W., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Seventh District of the Parish of St. Mary, Lambeth.

POPE, H. F. M., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the First District of the Malling Union.

SMITH, G., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Ford District of the Glendale Union.

SMITH, J. E., M.R.C.S., L.S.A., has been appointed Medical Officer for the Fifth District of the Malling Union.

TAYLOR, THOMAS, L.F.P.S.Glas., L.M., L.S.A., has been appointed Medical Officer of Health for Mile-end Old Town.

THOMAS, J. L., M.D., has been appointed Physician to the Royal South Hants Infirmary.

WALKER, R., M.D., has been appointed Medical Officer for the Wooler District of the Glendale Union.

Births, Marriages, and Deaths.

BIRTHS.

COOKSON.—On the 1st inst., at Eastbourne, the wife of Surgeon-Major Cookson, of a son.

CROOKSHANK.—On the 30th ult., at Yaldham, Kent, the wife of Edgar M. Crookshank, Esq., M.B.Lond., of a daughter.

LEFTWICH.—On the 5th inst., at The Limes, Brixton-road, S.W., the wife of Ralph W. Leftwich, M.D., of a son.

LEWERS.—On the 30th ult., at Wimpole-street, Cavendish-square, W., the wife of Arthur H. N. Lewers, M.D.Lond., of a daughter.

MORRIS.—On the 27th ult., at Devonshire-place, Brighton, the wife of John Morris, M.R.C.S., of a daughter.

NUNN.—On the 2nd inst., at Feckenham, near Redditch, the wife of J. R. Nunn, M.R.C.S., L.S.A., of a son.

RAKE.—On the 5th inst., at Herne-hill, the wife of Benven Neave Rake, M.D.Lond., Government Medical Officer, Trinidad, of a son.

WALKER.—On the 5th inst., at Hotham House, Putney, the wife of Alexander Walker, M.D., of a daughter.

WHITE.—On the 29th ult., at Winchester, the wife of Surgeon-Major Charles White, Army Medical Staff, of a son.

MARRIAGES.

CLABBURN SPAGNOLETTI.—On the 30th ult., at the Parish Church, Marylebone, T. George Clabburn, M.R.C.S., to Charlotte Ellen, eldest daughter of Charles Spagnoletti, Esq., of The Poplars, Aberdeen-place, N.W.

DAVIES—AIRD.—On the 1st inst., at St. Mary's, Pembroke, Arthur Mercer Davies, Surgeon, Army Medical Staff, Netley, to Evelyn Charlotte Aird, youngest daughter of the late Capt. David Aird, R.N., of The Anchorage, Pembroke.

DOBIE—ROSS-CHURCH.—On the 7th inst., at the Parish Church, St. Marylebone, by the Rev. F. Braithwaite, Stanley Locker Dobie, Surgeon-Major, 4th Madras Cavalry, to Violet Theodora, third daughter of Colonel T. Ross-Church, and granddaughter of the late Captain Marryat, R.N.

LAWRENCE—JOSEPH.—On the 30th ult., at the Bayswater Synagogue, Lourie Asher Lawrence, M.R.C.S., to Lizzie, eldest daughter of I. S. Joseph, of Clapham, and adopted child of H. S. Joseph, of Queensborough-terrace.

MASON—ROBERTS.—On the 30th ult., at Grafham, Huntingdonshire, John Mason, M.B., M.R.C.S., of Windermere, to Amy Isabella, only daughter of the late Colonel G. B. Roberts, Madras Light Cavalry.

SCARTH—MASTERS.—On the 6th inst., at St. Mark's Church, Lewisham, S.E., Isaac Scarth, M.B., B.S.Lond., to Rose Marion, daughter of the late G. C. Masters, of Lewisham.

DEATHS.

DEARDEN.—On the 27th ult., at his residence, Lytham (after a long and painful illness), James Dearden, M.R.C.S., L.S.A., in his 56th year.

EBDEN.—On the 14th ult., at Haughley, Rondebosch, near Cape Town, Henry Anderson Ebden, M.D. (late Bengal Medical Establishment, H.E.I.C.S.), President of the Medical Committee, in the 62nd year of his age.

TITLEY.—On the 30th ult., James Titley, M.D., of Brigg, Lincolnshire, aged 45.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Letters requiring notice must be authenticated by the name and address of the writer.

We cannot undertake to return MSS. not used.

ALCOHOL IN HOSPITALS.

THE Secretary of the Middlesex Hospital objects to the statement of the *Irish Temperance League Journal* as to the proportion of alcohol used by patients and officials respectively in the hospital. He declares that the calculation attributed to him was never made. We entirely accept his correction, and trust our temperance contemporaries will do the same. They are always and properly demanding accuracy of data and inference in this important question, and it would be a great mistake if they sought to enforce their views by using a disowned and unauthorised statement. It must tend to disturb Mr. Green's mind that such a statement was part of the infirm ground on which he based the justification of his wasteful destruction of good port wine.

Orthographer.—Both forms of spelling are in use, and either is correct, though "whooping-cough," as being more expressive of the forcible inspiratory act characteristic of the disease, is now usually adopted.

PONDEROUS BREASTS.

To the Editor of THE LANCET.

SIR,—I have a patient who suffers from great pain round the waist, and in the breasts almost constantly, due to the size of her breasts, which are unusually large. She complains that they make her life a burden to her, and constantly entreats me to amputate them. Would this be justifiable? Their weight produces a constant dragging pain from the clavicle downwards, and from the back and sides forwards, relieved when the weight of the breast is supported. Is there any known means of causing the breasts to contract by the application of any drug? If their weight and size could be greatly reduced it would be a boon. If any of your readers can from experience of a similar case suggest a trustworthy line of treatment I shall be most grateful.

I am, Sir, your obedient servant.

June 30th, 1886. M.B.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your report of the discussion on Mr. Brudenell Carter's paper on cataract extraction (June 26th, page 1232), I am reported to have said that I had performed Mr. Anderson Critchett's operation "in severe cases." Instead of "severe" *sereus* was what I said.

Believe me, Sir, faithfully yours,

Leicester, July 6th, 1886. FRANK H. HODGES.

THE PROGRESS OF CHEMICAL SCIENCE IN JAPAN.

FROM the annual report of the Tokio Chemical Society which was recently presented it appears that the study of chemical science is making rapid progress in Japan. Ten ordinary meetings and one annual meeting were held during the year, at the latter of which an important paper on the "Constitution of some Non-saturated Oxygenous Salts" was read. The Society has undertaken to translate chemical terms into Japanese, and it now possesses a dictionary of the commoner chemical terms in Japanese, English, French, and German. It has also undertaken to establish a system of chemical nomenclature in the Japanese language, of which the nomenclature of elements and of inorganic compounds is already nearly finished.

E. A. P.—The case mentioned appears to come distinctly under Art. 182 of the General Consolidated Orders, and the fee could no doubt be recovered in the county court. As an alternative course, pressure might be put upon the Local Government Board, either through the Poor Law Medical Officers' Association or by means of a question put in the House of Commons.

M. PASTEUR'S CURE OF HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—Having during the past week seen more than 250 inoculations performed in the Rue Vaugelin, and read over a number of the histories of patients operated on by Dr. Roux, I have come to the conclusion that there is no longer any reasonable doubt of the immense advance made in therapeutics by M. Pasteur's process for the cure of hydrophobia. The statistics are so telling that no one, I think, can read them without feeling convinced that an all-important discovery has been made. M. Grancher, whose abilities as a physician all are aware of, takes the date of April 22nd, 1886, as the one which allows of his drawing a conclusion warranted by the length of incubation of hydrophobia, and then shows that M. Pasteur has treated ninety-six cases of persons who had been bitten by dogs which were proved to be rabid because other animals bitten by them had died rabid, or because rabbits inoculated from their brain and spinal cord had succumbed to the disease. Of these ninety-six cases there was only one death. Again, of 644 cases of bites by dogs which were certified as rabid by the veterinary practitioner of the commune when they were bitten, only three of those treated died. Taking these two groups together, the death-rate of those treated was only 0·75 per cent., against 16 per cent., which is the death-rate assigned to a similar set of cases by M. Leblanc, Veterinary Surgeon of the City of Paris, when patients had been treated by other methods. In addition to these, M. Pasteur has treated forty-eight persons bitten by rabid wolves, and seven of these, or 14 per cent., have died, whereas the death-rate of persons bitten by wolves has been shown by M. Brouardel to be 66·5 per cent. Putting these facts together, M. Grancher contends with truth that Pasteur's treatment is twenty-three times as successful against the bites of dogs as the treatments of past times. I may add that the treatment seems to me to be perfectly and absolutely innocuous, and that the only pain felt by the patient consists in the prick given in the abdomen by the injection syringe ten times on ten consecutive days. The process, too, of inoculating the rabbits is now so simplified that there can be not the slightest reason, except popular prejudice, why M. Pasteur's inoculations should not be performed in every country. All that is required is that an inoculated rabbit should be imported, and then that other rabbits should be inoculated from it at its death. In this way the practice of inoculation might become at once generalised in every civilised country so long as rabies exists, which, of course, it will not do when the muzzling of dogs is as well carried out as it is in Berlin and North Germany. In the meantime all persons bitten by suspicious dogs should without any delay avail themselves of the noble offer of M. Pasteur to cure them of the most fatal of all diseases.

I am, Sir, your obedient servant,

C. R. DRYSDALE, M.D.,
Senior Physician, Metropolitan Free Hospital of London.

Paris, June 3rd, 1886.

P.S.—This morning 192 patients were inoculated by M. Roux at the Rue Vaugelin.

THE COVENTRY PROVIDENT DISPENSARY.

To the Editor of THE LANCET.

SIR,—In your current issue (p. 16) I see the above institution spoken of as "one of the sound and old-fashioned provident dispensaries which prospers." Four medical men receive an average of £347 per annum, which sounds well; but whenever I have visited Coventry—and that has been frequently over a series of years—I have heard numerous complaints about the dispensary, as most damaging to the profession, by including for cheap attendance a large number of well-to-do people. If the actual facts could be ascertained through your columns they would be interesting.

I am, Sir, yours obediently,

July 4th. A CONSULTANT.

"HOW NURSES CAN HELP."

A. P. ROCHE wishes to correct an error which occurred under the above heading in THE LANCET of July 3rd. It was not the household of the Earl of Howe from which her collection was made, but that of the Earl of Home.

Subscriber.—The Brussels M.D. can be so registered.

THE LATE DR. J. S. RIDLEY OF PRESTON.

WE have been asked to mention that an appeal is being made on behalf of the late Dr. Ridley's widow and two daughters, who have been left in straitened circumstances. The circumstances appear to be such as to call for the practical sympathy of the profession. Mr. H. A. Smith, of Burnham Lodge, Ealing, W., will be glad to receive subscriptions to the fund which has already been opened.

SHIP SURGEONS.

To the Editor of THE LANCET.

SIR,—It is not my wont to rush either into print or controversy, but the remarks of your correspondent, "M. A. P.," in your issue of June 26th, being so utterly at variance with my own experience of ship-life, which is of some duration, I cannot let them pass without comment.

Concerning precedence, a surgeon has, and always must have, absolute control of his own department; and knowing this, why should he trouble whose name is first on an often varied list, or wish to infringe on the purser's undoubted right to arrange passengers' seats? If "tagrag and bobtail" (to quote "M. A. P.") are placed next to him, a little healthy "chaff" in the right quarter will prevent such a thing happening a second time. Concerning vaccination fees, they are a matter of agreement with a company beforehand, and therefore cannot be grumbled at; but I have never known a case of a surgeon going short of passengers' fees if he has any scope at all, or is deserving of them. His sanitary reports, if thorough without being vexatious, will seldom be challenged, and I think it would be an unusually bold captain who, knowing the importance of patients being seen at all times, would take the grave responsibility of keeping his surgeon off the quarter or any other deck, and am sure that if the medical officer had any self-assertion such a thing would be impossible, unless from reasons of general misbehaviour. Members of our profession find themselves employed professionally on the ocean from several causes, the chief one, I believe (and hope), being for health's sake; and, I think, in the vast majority of cases, are on the best of terms with their brother officers, for such they are for the time being. If a general system of give-and-take is acted upon, it will be an exceptionally small ship that will not be large enough for every one within his due and lawful right.—I am, Sir, yours faithfully,

W. T. HARRIS, Surgeon.

R.M.S. *Hawarden Castle*, East India Dock, E., June 29th, 1886.

"AN APPEAL."

To the Editor of THE LANCET.

SIR, Referring to my appeal in your issue of the 26th ult., for the insertion of which allow me to thank you, I regret to say that it has not been responded to in a manner in which I hoped it would have been. I sincerely trust that those of your readers who have overlooked this appeal will kindly respond thereto. Up to the present time I have received the following liberal sums:—

Sir Prescott Hewett, Bart.	£5	5	0	Dr. O. Hagershon ...	...	£1	1	0
R. Fitzroy Benham, Esq....	5	5	0	Dr. T. Lauder Brunton	...	1	1	0
Sir J. Lister, Bart. ...	5	0	0	Signa...	...	1	0	0
Thomas Smith, Esq. ...	5	0	0	Dr. Ewart	...	0	10	0
Sir James Paget, Bart. ...	3	3	0	E. J. Newcastle ...	...	0	10	0
H. Stear, Esq.	2	2	0	Lady Estcourt ...	...	0	5	0
Sir Andrew Clark, Bart....	1	1	0	H. J. Latimer, Esq.	...	0	5	0

I am, Sir, yours faithfully,

R. FITZROY BENHAM.

Abercorn House, Baron's Court, S.W., July 5th, 1886.

THE RELATIONS OF POOR-LAW MEDICAL OFFICERS TO BOARDS OF GUARDIANS.

To the Editor of THE LANCET.

SIR,—I am requested to inform you that at a Council meeting held on July 1st, 1886, it was resolved that a memorial should be forwarded to the Local Government Board, asking for a reconsideration of the case of Mr. A. B. Simpson, in reference to the late Poor-law inquiry held at the Birmingham Workhouse, when Mr. Simpson was called upon to resign through offending certain of the guardians, by not obeying a verbal order conveyed to him by the chairman of the visiting committee, which practice, if carried out, the Council considered would lead to disaster and confusion.—I am, Sir, yours truly,

J. WICKHAM BARNES, Hon. Sec.,

Poor-law Medical Officers' Association, 3, Bolt-court, Fleet-street, E.C., July, 1886.

"TOO BAD."

THE Hon. Secretary of the Home Hospitals Association presents his compliments to the Editor of THE LANCET, and begs to inform him, with reference to the paragraph headed "Too Bad," on page 58 of the issue of July 3rd, that (1) no general collection was made at the Home Hospital for Hospital Sunday. The patients were reminded of the day and were left entirely free to choose where they would send their contributions. (2) The staff do not attend St. Mary Magdalen, Munster-square; but on Hospital Sunday one of the patients sent her contribution to that church, when she learnt that there was no collection there for hospitals.

Dr. Pierce (Manchester).—Yes, so far as our space will permit.

BASILY DISINFECTED INSTRUMENTS.

DR. VON HEYDENREICH of Moscow has published a pamphlet showing how surgical instruments which are to be used for antiseptic operations can be made as far as possible of one piece of metal. He has planned pocket and field cases for general and military purposes in which all the instruments are so constructed. They are, it is true, rather heavy, the complete set for military purposes weighing about 30lb. From the figures given, however, they would appear to be handy and suitable for the purpose for which they are designed. They are all made by Schwabe, of Moscow.

"THE VOLUNTEER MEDICAL SERVICE."

To the Editor of THE LANCET.

SIR,—In the annotation under the above heading in your issue of the 3rd inst., you state that so far as you know the bearer company now being organised under the able direction of Dr. J. W. Taylor, of Scarborough, in connexion with the 2nd Volunteer Battalion Yorkshire Regiment, is the first in the north of England. You will be glad to know that a similar effort has met with very gratifying success here, and that in this year's turn out for inspection as the nucleus of a bearer company upwards of fifty officers, non-commissioned officers, and men, all of whom possess ambulance proficiency certificates from the War Office, and half of whom are medical students connected with this College. The detachments did duty as a bearer company (not as regimental bearers) at the Gosforth Park review last month. The question of expense alone prevents immediate application for recognition as an independent company. Your annotation shows how dissociated the units of the Volunteer medical service are.

I am, Sir, yours faithfully,

W. P. MEARS,

Surgeon, Tynemouth Artillery Volunteers.

Newcastle-on-Tyne, July 6th, 1886.

IODOFORM SPRAY AND LOTION.

To the Editor of THE LANCET.

SIR,—I beg leave to offer an apology for my delay in replying to the gentleman who, in THE LANCET of June 26th, did me the honour of referring to my method of prescribing "emulsified" iodoform. His question was a very natural sequel to an error of your printer, who in the previous week had, by running into one the two words "tere" and "bene," made it appear that terebene was prescribed. The prescription should be as follows. ℞ Iodoformi præcipt., ʒ ss.; tr. senegæ, ʒ i.; rub well and add water up to one ounce. If a more stable "emulsion" be desired, or if it be for use in a spray apparatus, an improvement may be effected thus: Shake the above and filter it through muslin; allow the filtrate to stand some hours in a test-tube; pour off the fluid, and to the deposit of iodoform that remains add fresh tinct. senegæ and fresh water as before. Most of the chemists in this neighbourhood have kindly given the matter some attention, and dispense the prescription very well.

I am, Sir, your obedient servant,

Charlwood-street, Pimlico, S.W. ALFRED LEACH.

MEDICAL BOYCOTTING.

C. T. K. P.—We think there can be no difference of opinion in regard to the case as stated to us. We agree with our correspondent. Nothing in medical ethics forbids a patient a reasonable and good-tempered freedom in the choice of a medical attendant. Every medical man learns to recognise such freedom and to accept it.

Mr. G. H. De'Ath.—We cannot approve of a medical officership of health being put up for "tender," and endorse the position adopted by the gentleman who "maintained a dignified silence."

TREATMENT OF CYSTIC GOITRE.

To the Editor of THE LANCET.

SIR,—In your issue of the 3rd inst. is the report of a case of cystic goitre treated by Dr. C. T. Vachell, of Cardiff, by "shelling out," but there is nothing in the account to indicate that the case presented unusual features, and therefore required exceptional treatment. Although the operation was successful, it would be interesting to learn why a cure was not effected by the usual method (injection of a solution of perchloride of iron into the sac through a cannula, and its retention secured by means of a plug until suppuration has taken place), but an operation selected which not only entails a greater risk to the patient, but which must leave a larger scar, even if no other disfigurement results.—Yours truly,

Mansfield-street, W., July 7th, 1886. T. MARK HOVELL.

METALLIC CIRCULAR CLINICAL THERMOMETERS.

To the Editor of THE LANCET.

SIR,—With regard to the query addressed to those who have and are using the above, I wish to say that after a trial of six months I can bear my testimony to their value both as regards their general accuracy and their compact and convenient form. They will lie nicely upon the surface of the body, and, as they are quite air- and water-tight and retain no dirt about them, are perfectly convenient for insertion (for clinical purposes) into the mouth or elsewhere.—Yours truly,

Ampthill, July 4th, 1886. W. ARNOLD THOMSON.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Clinical Lectures
ON
CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

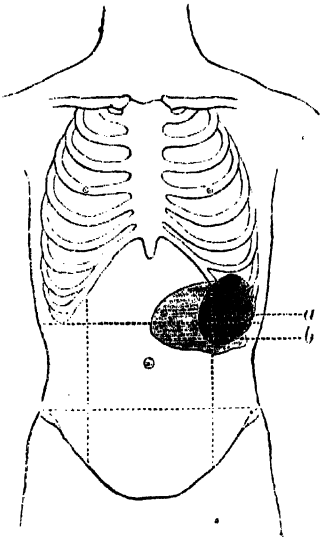
LECTURE VII.
ON GASTRIC AND PERIGASTRIC ABSCESSES.

GENTLEMEN,—We have hitherto been considering abscesses communicating with the intestinal canal, but in order to complete our survey of the whole subject of abscesses opening into the digestive tube, we must now turn our attention to those connected with the stomach. It will, however, in order to gain a clear idea of these affections, be necessary for us first to consider separately gastric and perigastric abscesses. The former are situated in the walls of the organ, and may or may not open into it; the latter are in the neighbourhood of the viscus, and communicate with it by an opening through its coats, or are the result of ulcerations in its interior. Gastric abscesses may present themselves either as a purulent infiltration or as a localised collection of pus in the coats of the stomach. The former have been occasionally observed as an accompaniment of an acute infectious disorder, more especially in puerperal cases, and under such circumstances they probably result from the absorption of pus. The latter are also very rare, only thirty-one cases of both forms having been recorded; but as some instances have fallen under my own observation, it is probable they are not so uncommon as is generally represented. In the cases I have seen there has been always thickening of the walls of the stomach, either by malignant disease or as the result of previous inflammation; the pus has been situated in or near the newly-formed structure, and the mucous membrane has presented numerous small openings through which the pus could be readily squeezed. We occasionally meet with patients who assure us that they have been suddenly relieved of epigastric pain by the vomiting of pus, but considering how easily mistakes may be made between pus and other secretions, we are not justified in accepting such statements as evidence of a gastric abscess. Leube, after an examination of the various recorded cases of gastric abscess, has laid down the following as the symptoms of the disease. "In the midst of perfect health, or after a period of general malaise, the individual is seized with pain in the stomach and vomiting, accompanied by thirst, dry tongue, small frequent, and irregular pulse, meteorism, and diarrhœa; subsequently delirium and prostration ensue, and finally death."[1] Now, unfortunately, in the cases I have seen there were no symptoms pointing to any change in the condition of the patient that would lead us to suspect an abscess of such an important organ. The following is the last case that has fallen under my notice.

CASE 1.—A man of middle age was admitted into the hospital with the ordinary symptoms of acute pneumonia. His wife stated that he had been unable to work for the last three years, on account of gradually increasing debility, and that he had daily vomited a quantity of clear fluid, but had not been in the habit of vomiting his food. On post-mortem examination, in addition to the pneumonia, the pylorus was found to be greatly thickened, and the stomach somewhat, although not excessively, dilated. There was a small ulcer, apparently of recent formation, near the pylorus, at a part where the coats were extremely thin and wasted, the rest of the mucous membrane in that region having a tough, fibrous appearance. In the thickened pylorus there was a collection of pus which could be easily squeezed through numerous minute holes with which the mucous membrane was perforated.

Now in this case there was no complaint on the part of the patient of any pain in the epigastrium, and it was only after his death that we were informed of his previous impaired health. In the other cases I have seen there has been a similar absence of well-marked signs of suppuration, and we may, I think, seek for an explanation of this in the rapidity with which the pus makes its way through the numerous small openings that form in such cases in the mucous membrane of the stomach.

Abcesses occur in the left hypochondrium and epigastrium independently of any irritation in the stomach, or of a communication with that organ. Thus you will occasionally see them arising from a suppurating hydatid cyst, more rarely as the result of tubercular peritonitis, or from irritation set up in the liver, spleen, or kidneys. But the form of perigastric abscess to which I propose to limit my remarks is that which either commences in the stomach, or which afterwards forms a communication with that viscus. The following case which was admitted under my care will show how obscure the affection frequently is, and how very difficult it may be to recognise it.



CASE 2.—A man, aged thirty-eight, was admitted Jan. 31st, 1881. He was a weaver, and had enjoyed good health until "some time ago," when he began to suffer from indigestion, the food appearing to lie heavy on his stomach and producing great pain. He stated that he had suffered from an injury to the back, but its nature and the date are not mentioned in the notes, and he evidently did not attach any importance to it. He never had syphilis. On admission, he had an anxious expression and complained of very severe pain in the left hypochondrium, extending backwards round the left side as far as the spine. All this region was very tender on percussion, the most tender spot being opposite the tenth and eleventh ribs. He was unable to lie on his right side, so that he constantly lay on the left side, with the neck bent forwards and his knees drawn upwards. Pulse 90; temperature 99°. He had no appetite, the tongue was thickly furred, and the bowels obstinately confined. The liver dulness extended from the fifth costal interspace to below the ribs, and it was slightly tender on pressure. Abdomen generally resonant. In the left hypochondrium, dulness on percussion extended upwards to the heart's apex, and downwards to a level with the umbilicus. Chest normal. The heart's apex was not raised, and there were no murmurs. On Feb. 10th he had constant vomiting, and he complained of the severity of the pain, extending from the left hypochondrium to the spine; the breath was very offensive; he could take no food; the pain was increased directly he attempted to take any food, but it was also continuous, and increased at night, preventing sleep. The recti muscles were hard and rigid. On the left side near the spine there was dulness on percussion, but no increased pulsation, and no murmur. He had constant nausea, increased even after a drink of water. It is noted on Feb. 15th that a hardness could be felt below the left hypochondrium, and an elongated dulness on percussion in the left hypochondrium, measuring three inches longitudinally by six laterally. (See Fig. 1.) The lower border of the liver was also remarked scarcely to descend on full inspiration; there was also some dulness on percussion, and increased resistance to pressure immediately above the umbilicus. The man continued in much the same state until April 22nd. The pain was excessive and constant, and required the use of subcutaneous injections of morphia frequently in the day. He had steadily lost flesh, and was then only 6 st. 12 lb., having weighed 8 st. on admission. The temperature varied from 98° to 100° during February, but rose to 102° in March, and afterwards oscillated until April 22nd, at which date it rose to 103°, and the patient complained of great pain at the base of the lungs behind, although neither dulness nor friction sounds could be discovered. On the 27th, he had a severe rigor, the temperature rising to 106°; but the pain in the left side was not more severe than usual. The left chest was now found to be dull on percussion, with absence of breath sounds, diminished vocal and tactile fremitus, but no friction sounds could be heard. On the 29th he had severe and general sweatings, the dulness was much increased in the left hypochondrium, but the tenderness was not increased, and the pain had diminished. Friction sounds were first discovered on May 2nd near the apex of the heart; rigors recurred from time to time, and a herpetic eruption showed itself on the lips, palate, and roof of the mouth. After this period the appetite began to improve, the pain decreased, and his weight remained stationary. On May 12th friction sounds could be heard over the whole left hypochondrium, where there was formerly such marked dulness on percussion, the dulness at the back of the lung slowly diminished, and the pain gradually lessened, until it only came on after food. From

[1] Ziemssen's Cyclopædia of the Practice of Medicine, vol. vii., p. 161.

this time he rapidly improved, the pain entirely left him, the appetite returned, and he gained (so the notes state) as much as six pounds in weight in a single week. On June 22nd he was discharged, after being in the hospital five months, and at that time there was no dulness at the base of the lung and no friction sounds; there was some fulness under the left hypochondrium, but the part was tympanitic on percussion.

There must, of course, be always a certain amount of doubt about any case in which a post-mortem examination has not confirmed the accuracy of the diagnosis, but by taking into consideration the termination as well the course of the disease we may in most instances arrive at a correct decision. In the foregoing case it will be necessary for you to bear in mind that the patient had suffered from symptoms of gastric ulcer for some time before he entered the hospital; that on his admission the pain had become constant, although it was still increased by food; and, in addition to this, that an ill-defined tumour could be distinguished below the ribs, whilst on percussion a dull space was found both before and behind in the region of the stomach. He remained in this state for about three months, having lost a stone in weight, and the pain being so severe that the constant use of hypodermic in-

FIG. 1.

Plan of case of Perigastric Abscess. *a*, Part dull on percussion; *b*, part tympanitic on percussion.

jections was required to alleviate it. At the end of that time severe rigors ensued, accompanied by effusion into the left chest, although the pain did not increase, and no friction sounds were heard until ten days afterwards. After this he gradually improved, gained a stone in weight, and although the pain after food persisted for some time, it eventually disappeared. There was afterwards a friction sound to be heard in the left hypochondrium, where there had been formerly the dulness on percussion, but this also became gradually inaudible. Now this was clearly not a case of cancer, as was at first suspected, for there was no enlargement of the glands or liver, and the ultimate recovery of the patient negatives such a supposition. Neither was it an abdominal aneurysm, for you will remember it is stated there was neither a murmur nor pulsation, and the favourable issue is sufficient to disprove it. The undefined feeling of the tumour, and the dulness on percussion in front and behind, point to a collection of fluid rather than to a solid tumour, and this might arise either from a hydatid cyst or perigastric abscess. The former would not explain the pain after food, nor its persistence after the convalescence of the patient, whilst the latter seems to meet all the difficulties of the case. We shall afterwards find that this form of abscess chiefly occurs in chronic ulcers of the stomach, where adhesions have been formed, and you will observe that adhesions must have been present, for it is remarked in the notes that the liver did not seem to descend on full inspiration. The dulness, again, was clearly the result of an inflammatory exudation, for a friction sound could afterwards be heard in the locality where it was formerly detected. Then it is almost certain that perforation of the diaphragm occurred, and the pent-up pus made its way into the pleura, and this is a common accident in perigastric abscess. But in the diagram copied from the notes, you will remark there is a space in front of the dulness that was tympanitic on percussion, and you might suppose this was distended with gas, as is so common in perigastric abscess; but if such had been the case we should have had pneumothorax when the perforation occurred, so that the idea must, I think, be dismissed. You will, however, be able better to appreciate the probabilities of diagnosis being correct if we now discuss in greater detail the subject of perigastric abscess.

Perigastric abscess of the kind to which I have limited our inquiries is a very rare form of disease, for I have only discovered eight instances of it in the post-mortem records of this hospital. In all of these the walls of the abscess were formed by adhesions of the neighbouring viscera; in five ulceration of the stomach and in three a cancerous tumour were present; in one of the latter an opening had taken place through the abdominal walls. I have been able to collect only forty-four other cases from various authors, but I hope these will suffice to enable me to lay before you some of the chief circumstances connected with the disease.

When we were considering the subject of abscesses connected with the duodenum, we found that in a certain proportion their walls were formed of connective tissue; but it is evident that, from the complete investment of the stomach by the peritoneum, such is not likely to be the case with a similar affection of this organ. We consequently find that in the majority of cases the abscess was walled in by adhesions of the liver, spleen, or colon with the stomach, and that the pus was situated in front of this latter organ; in only four the abscess was situated behind it, in two it was placed in the right hypochondrium, and in three the ribs of the left side formed part of its walls. Of fifty-two cases, nineteen, or more than one-third, are stated to have been in contact with the diaphragm, and, as we shall afterwards see, perforation of this muscle is a common consequence of the disease. A foreign author has attempted to explain the frequency of the situation of perigastric abscess on the supposition that the distension of the intestines that always accompanies peritonitis pushes the pus upwards; but I think it is more probable that, as the perforation of the stomach usually occurs in its smaller curvature, the inflammation must necessarily generally commence in this locality, and where this is not the case, the upward movements of the diaphragm must tend to draw the pus upwards, whilst the descent of the muscle is unable to depress it on account of the adhesions that are already present between the contiguous organs. Occasionally the abscess is situated in the lesser omentum, but there are very few cases on record. It is worth while therefore to record the following.

CASE 3.—A man, aged forty-seven, was received into the London Hospital, under the care of Dr. Hughlings Jackson,[2] with a history of having suffered from pain of the abdomen for eight or nine years; he had never had hæmatemesis or vomiting of food. The day previously he was attacked with constipation, for which numerous enemata had been administered without effect. He complained of extreme pain over the abdomen and great dyspnœa, but died four hours after his admission.

Post-mortem examination.—"The mesentery attached to the upper part of the jejunum was covered over with puriform lymph; the upper and transverse parts of the meso-colon were also coated with lymph. On separating the colon an abscess was exposed lying in the cavity of the lesser omentum, bound in by the jejunum and colon and under the liver and back part of the stomach. The left end of the stomach was much thickened, and on opening the organ a large ulcer was found at the œsophageal end, near the lesser curvature and in the posterior wall. It was about an inch and a quarter in diameter, and had a firm grey floor, with round thick edges. At one spot it had perforated the coats of the organ and communicated directly with the abscess. The bronchi were filled with pus derived from the abscess."

[2] I beg most heartily to thank my colleagues who have so kindly placed the notes of their cases at my disposal.

Of fifty-one cases of perigastric abscess in which there is clear evidence as to the cause, six were associated with cancer, four with abscesses commencing externally to the organ, whilst forty-one were due to the irritation of simple ulcers.

You are well aware that gastric ulcers are more common towards the pyloric than the cardiac end of the stomach, but of nineteen in which the site of the ulcer coexisting with a perigastric abscess is recorded, eleven were at the cardiac and only eight at the pyloric end. Of sixteen in which the position of the ulcer is stated as regards the curvatures, thirteen were on the smaller and three in the larger; whilst three were on the anterior and five on the posterior wall. The unusual number of the ulcers in these cases at the cardiac end suggests the suspicion that the greater fixity of this portion of the stomach may be the reason why localised abscess was more prevalent in this situation than at the pylorus. This seems to be supported by the fact that adhesions, apart from those forming the walls of the abscess, are often mentioned as existing between the stomach and some of the neighbouring organs, and that very frequently the perforation had taken place at the point where the parts were thus united. Twenty-two cases of adhesion are recorded, and as no doubt this matter had often escaped observation, they were probably present in the greater number of those affected with this form of abscess. In some the small size of the perforation is expressly mentioned, and in five instances no communication could be found between the abscess and the ulcer, although they were in close proximity. The conclusion in such instances has been drawn that the perforation had healed after the formation of the abscess, but I would throw out the suggestion that in some of these cases there may have been an abscess originating in the coats of the stomach itself, which had set up suppuration by discharging its contents externally. There is another supposition worthy of consideration—viz., whether an inflamed ulcer of the stomach may not be able to set up suppuration in newly-formed tissue external to it, in the same way as we before found, in some of the cases of perinephritic abscess, suppuration was produced around a tubercular kidney, although the capsule of the organ remained intact. The following case seems to show that an abscess of this kind may also originate in pyæmia:—

CASE 1.—A man, aged forty-seven, was admitted under the care of Dr. Stephen Mackenzie. Eighteen months previously he had suffered severe pain in the epigastrium, increased one hour after food; one month ago he was attacked suddenly with severe pain of the abdomen, having for two or three days before been greatly constipated. A mass the size of a cricket-ball was discovered on the left iliac fossa, which was nodular and painful on pressure; dulness on percussion and distant breath sounds were also found at the base of the left chest. A few days afterwards the abscess was opened and eight ounces of very fetid pus were evacuated. This was, however, followed by erysipelas, and as his breathing became difficult, the left chest was aspirated and forty ounces of pus removed."

Post-mortem examination.—It is stated that there "was contraction of the descending colon and an abscess in the abdominal walls," but the notes on this point are very scanty. "There was also an irregular contraction of the stomach around a point midway between the cardiac and pyloric ends, and at the base of this a circular depression where it was adherent to the left lobe of the liver. External to the adhesion, there was a small abscess below the stomach, left lobe of liver, and diaphragm. The stomach was much thickened around the ulcer, and an abscess the size of a hen's egg was situated below the capsule of the spleen. The left pleura contained pus."

You will observe here that the patient had suffered from symptoms of gastric ulcer for eighteen months, but the formation of pus, which was small in quantity, had in all probability only taken place recently. As it was accompanied by an abscess in the spleen and in the abdominal walls, and pus was also found in the left pleura, it is most probable that they were all due to a common cause—viz., to pyæmia resulting from the abscess in the iliac fossa.

When the state of the ulcer is mentioned, it is in all cases such as accompanies one of long duration, and in some the perforation is said to have taken place in the cicatrix of an old ulcer. The coexisting conditions of the organ itself point to the same conclusion. Thus, in four the stomach was much contracted, in three the coats were thickened, in two it is mentioned as dilated, in one there was narrowing of the duodenum, in one of the œsophagus, and in three of the pylorus.

The facts we have now ascertained will, I think, suffice to show under what circumstances a perigastric abscess is most likely to take place—viz., when adhesions have occurred between the stomach and some of the neighbouring organs, and the ulceration either proceeds very slowly to the surface, or the perforation is so minute that only a very small portion of the gaseous or liquid contents of the organ finds its way into the space limited by the adhesions. Such conditions are of course most likely to occur when the coats of the organ have been thickened by long-standing disease, and when the ulceration is situated at some place that can most readily contract adhesions to the neighbouring parts. In thirty-four of the cases collected the pus eventually made its way either into the cavity of the chest through the abdominal parietes or into one of the neighbouring organs. When you remember the power of the gastric fluid of digesting animal substances, you will be tempted to ask whether this unusual tendency to perforation of the neighbouring structures may not be partly the result of the contents of the abscess being in communication with the interior of the organ. In support of this one case may be quoted in which no remains of the pancreas could be discovered, its site being occupied by the pus; and in two others the opening of the stomach into the pleura is stated to have been very large. But, putting aside these cases, there is not much evidence in favour of such a supposition, for the openings into the stomach are generally recorded as being very small, and no appearances similar to those of post-mortem digestion have been noticed. This probably arises from the fact that the communication between the stomach and the sac was not very free, or the whole contents of the latter would have been discharged through the canal. As a consequence of this, little or no gastric juice would become mixed with the pus, and thus the vitality of the neighbouring structures would be a sufficient protection. It is, however, evident that in cases of this kind there is a great tendency to decomposition, arising probably from the entrance of gas and other products of fermentation from the stomach, for the pus is usually described as "ichorous"; in three instances the spleen was found to be greatly softened, in six there was pneumonia, and in two there was also gangrene of the lung.

We before found that the greater number of perigastric abscesses were in immediate contact with the diaphragm, and it is therefore not surprising that the cavity of the chest has been more frequently perforated than any other part. This occurred in twelve of those I have collected, and where there was a communication with the stomach of course both air and fluid were present in the pleura, but in cases, such as we have before seen sometimes occur, where there was no direct opening into the organ, pus alone was met with. Occasionally adhesions had taken place in the pleura, dividing it into separate compartments filled with pus; but this was a very unusual condition. You will remember that we remarked in a former lecture that perinephritic abscesses were also liable to perforate the diaphragm, and it will naturally strike you as strange that this should be so common in abdominal abscesses, whilst, as you know, perforation from the chest into the abdomen is unusual. The reason of this difference I believe to be that in empyema the fluid has a ready means of escape by perforation of the lung or the intercostal spaces, whilst in the abdomen it is pent up by adhesions, and closely surrounded by organs with thick and vascular coats. But empyema was also sometimes present even where perforation of the diaphragm was not discovered; and the most reasonable explanation of this is that some of the contents of the abscess were absorbed by the lymphatics of the diaphragm, which, as you are aware, are very large and active in this structure. Considerable difference existed as to the liability of the sides of the chest to perforation, it having been recorded in ten cases on the left, and in only two on the right side; but this, of course, arises from the greater number of abscesses being situated in the left side of the abdomen.

I have only found three cases in which perforation of the pericardium took place, the entrance of the fluid, of course, setting up sudden and violent inflammation of the membrane.

In twelve cases perforation of the abdominal parietes is recorded, the pus being discharged externally, and leaving a communication between the surface of the body and the stomach. Seven of these seemed to have originated in

gastric ulcer, one in cancer, whilst in four the abscess commenced outside the stomach, but afterwards perforated its coats. This termination of perigastric abscess is extremely rare, and many seem to have been placed on record only because they are so uncommon. I find the following example in our post-mortem books, but I have been unable to obtain any history of the patient during her life.

CASE *b*.—The patient was a female, aged thirty-five, admitted under the care of the late Mr. Maunder. "An incised wound to the right of the umbilicus communicates with a large sinus-like cavity. Beneath the left lobe of the liver, and in front of the stomach, is a quantity of reddish grey, juicy substance, which looks like encephaloid cancer. On a level with the incised wound the abdominal wall is adherent to the omentum, and this firm adhesion encloses the liver, stomach, and upper part of the duodenum in one cavity. The colon is empty and does not communicate with it. The small intestines are normal. A bougie is seen to pass from exteriorly into the stomach at the pyloric extremity, and this fistulous opening admits the introduction of a finger, so that the contents of the stomach must have escaped out of the abdominal walls. The pyloric end is invaded by cancerous masses, its surface being irregular and ulcerated. Close to the pylorus, at the greater curvature, the walls of the stomach are absent, having been completely destroyed by the cancerous ulceration, and it is here that the external opening communicates with the organ. A little to the right of the opening the stomach is contracted by firm fibrous thickening, and only admits two fingers. The glands along the spine are cancerous."

The foregoing is a good illustration of the terrible destruction often wrought by gastric cancer; but, as a rule, the formation of an abscess is not common, the morbid growth tending to invade and consolidate the neighbouring structures, instead of inducing suppuration. Still, you must remember that the formation of pus does occasionally occur, for I lately diagnosed tubercle of the peritoneum chiefly on the ground of the presence of an abscess under the abdominal walls, but post-mortem examination showed I was wrong, and that it was the result of malignant disease.

Perforations are noted as having occurred into most of the neighbouring hollow organs; thus in one instance the stomach, duodenum, and colon communicated with the same abscess, in seven there was an opening into the colon, in one into the small intestine, and in one into the gall-bladder. In eleven there was more than one ulceration in the stomach, and in some instances more than one ulcer opened into the same abscess. The sex was recorded in forty-one cases of perigastric abscess arising from ulcer, and of these twenty-five were females. Dr. Brinton concluded from his inquiries that females were twice as liable as males to gastric ulcer, so that if we can trust to so small a number of cases as I have collected, males are more apt to have epigastric abscess than the weaker sex. The ages are given in thirty-seven cases of perigastric abscess, and I have compared in the following table the percentages at different ages with those given by Dr. Brinton of 226 cases of gastric ulcer.

	Under 20.	20 to 40.	40 to 60.	Above 60.
Percentages of gastric ulcer	9	37	31	23
Percentages of perigastric abscess	19	56	19	6

YOU will here see the greater proportion of cases of perigastric abscess in the earlier period of life, when the vital powers are strongest, and when there is, therefore, the chief tendency to adhesive inflammation, the greatest number occurring between twenty and forty, and very few presenting themselves after sixty years of age. It seems to point to the same conclusion at which we before arrived viz., that the main predisposing cause of the disease is the formation of adhesions which, in case of perforation, prevent the escape of the contents of the stomach into the general cavity of the peritoneum.

(To be concluded.)

COLONIAL LEGISLATION FOR THE HABITUAL DRUNKARD.—In his address as chairman at the British and Colonial Temperance Congress, at the Princes Hall, this week, Dr. Norman Kerr stated that in Canada, South Australia, Victoria, and New Zealand, the habitual drunkard could be placed under care and treatment and restraint against his will. In this respect the Colonies were far ahead of the mother country. Colonial legislation was permanent, and not temporary, as at home.

EXCISION OF THE COCCYX.

BY WALTER WHITEHEAD, F.R.C.S.E., F.R.S.ED.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY, ETC.

THE following two cases which have recently occurred in my practice illustrate the advantages under certain circumstances of excision of the coccyx.

CASE 1.—X. Y——, aged fifty-nine, male, has for the last twelve years suffered from distressing pain in the seat. He has consulted various surgeons both in London and in the provinces, but without obtaining relief, and his various advisers had failed to diagnose any sufficient cause for his symptoms. I was asked to see the case with Dr. Livy of Bolton, the patient's private medical adviser, who told me that the case was one of ischio-rectal abscess suspected to be associated with some diseased condition of the coccyx. An examination confirmed this opinion, and I determined to cut down upon and investigate the condition of the parts. This I did two days after first seeing the patient. An opening which had been previously made into the abscess, above and just within the right tuber ischii, was freely enlarged, and a sinus leading into the rectum just above the internal sphincter was laid open. A second sinus was now found, which, on exploration with the finger, was ascertained to lead to a necrosed coccyx. An incision was then made immediately over that bone in the middle line, and through it were removed the last three segments. The wounds were thoroughly scraped so as to remove all unhealthy granulation tissue, and they were then plugged with iodoform gauze. Immediately after the operation, the temperature, which had previously ranged as high as 105°, fell to the normal, and never again rose above 100°, at the same time the general health of the patient improved rapidly. The pain from which he had previously suffered disappeared at once, and has not returned, and the wound healed well and rapidly.

CASE 2.—E. R——, aged thirty-seven, male, on consulting me, gave the following account of himself. His occupation is that of a piano dealer and tuner. For the last fifteen years he has been subject to attacks of pain, at first infrequent, at intervals of about a month, and not very severe; latterly these attacks have been as frequent as once or twice weekly, and his pain has been much more severe. The pain is always brought on by the commencement of the act of defecation and is in the region of the anus; when it occurs he has severe tenesmus and a desire to further empty the bowel, the pain meanwhile increasing in intensity, and often detaining him in the closet for two hours at a time. After such an attack more or less pain will remain throughout the day, and even during the whole of the following night. He can suggest no cause for the origin of these symptoms, except that he has always had a tendency to constipation. Some time since, however, he fell and struck the coccyx against a piano, but this appears to have been subsequent to the onset of the disease. He has hitherto found a certain amount of relief from the use of a warm sitz-bath, but this has not been of great efficacy, and all other measures have proved futile. On examination and especially on pressure over the posterior part of the rectum, pain is caused exactly similar to that induced by defecation. Finding that the seat of the pain was apparently the coccyx, and discovering that bone bent at a right angle, and having the history of an injury, I excised it by a median incision, without opening the rectum. The parts healed at once, relief from pain was complete, and there has been no return since the time of the operation.

In addition to these two cases in males, I had under my care, about ten years ago, five cases of coccygodynia in females, all produced by injury during parturition, and in all of which I removed the coccyx, with immediate and complete cure of the disease.

The treatment of coccygeal pain falls under three heads—viz.: 1. By means of rest and anodynes. 2. By complete or partial separation of the bone from its muscular connexions. 3. By excision of the bone. As in other cases, our method of treatment must always be guided by the nature of the case. Thus in those where the pain is due to hysteria or to reflected irritation, owing to uterine or ovarian disease, it would obviously be unsurgical to remove the coccyx. There are, however, a large number of other cases, in which surgical interference will probably be required, and which may be

arranged under the following heads: Old fractures and dislocations, in which the bone has become fixed in a faulty position, either that of flexion or of extension; congenital elongation of the coccyx; necrosis, whether traumatic or otherwise; tumours connected with the coccyx; and, finally, a large group of cases of obscure pathology, in some of which there appears to be periostitis of some or all of the segments, in others inflammation of the sacro-coccygeal joint.

In an old fracture or dislocation with displacement, we can hope for no improvement apart from operation, and here also Simpson's operation of separation of the attached muscles cannot be expected to succeed in relieving the patient. Skey[1] attempted to remedy an old dislocation backwards with consequent extreme flexion of the coccyx, by means of traction made by passing a loop of wire over the apex of the bone and connecting this loop with a splint attached to the spine; but the pain produced by this method was so great that it had to be abandoned. It might appear possible in such cases to separate the displaced bone at its abnormal angle, and endeavour thereafter to retain it in position by a plug introduced into the rectum, but the difficulty of preventing a return of the displacement must necessarily be great, if not insuperable. Hence in such cases I should advise excision of the bone.

Further, if congenital elongation be a cause of pain, removal of the part is clearly indicated. So also in cases of necrosis, as in the first of my patients, we are following the ordinary surgical method in removing the sequestrum. Cases of tumour involving the coccyx must be treated on general surgical principles. But it is in cases where there is no obvious lesion that there is the greatest room for diversity of opinion as to the method of treatment to be adopted. Here we would naturally try, before resorting to operation, the effects of rest and of the various anodynes. But if this treatment should fail, as it had done in my cases before they came under my observation, what is to be done? Hilton recommended separation of the fibres of the sphincter ani from the apex of the bone, and thus undoubtedly made possible more perfect rest. Simpson went further and completely divided the muscular connexions of the coccyx by means of subcutaneous section, and he was thus able to cure a considerable number of cases. But he himself admits that in some instances this operation was insufficient, and he then resorted to the procedure, which had long before been advocated by Nott, of removal of the coccyx. In nearly all cases the latter method seems to have effected a cure, and I should therefore be inclined to adopt it at once instead of running the risk of wasting time by the subcutaneous isolation. The operation of excision of the coccyx is sufficiently simple and without danger: it is more easily performed than the subcutaneous division of muscles; its result is apparently universally good, providing that the diagnosis be correct; and the loss of the bone does not seem in any case to have caused inconvenience. On these grounds, therefore, I would advocate excision in all cases of coccygeal pain where non-operative treatment has failed to give relief, unless the pain be due either to some constitutional condition as hysteria, or to some reflex influence as of uterine and ovarian disease.

Manchester.

SIXTY CASES OF SCIATICA TREATED BY GALVANISM.

By W. E. STEAVENSON, M.D. CANTAB., M.R.C.P.,
ELECTRICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

SINCE publishing my paper in THE LANCET of Jan. 19th, 1884, on the Use of Galvanism in Sciatica, I have had sixty cases under treatment, and the results have borne out the hopes I then entertained as to its efficacy. I have therefore thought that the details of these additional cases might be interesting to the profession. My only purpose to give a very short account of each case, embodying the most important points. I gave a description of the mode of applying the current in my former paper.

CASE 1.—Jan. 24th, 1884. A lady, aged fifty, sent to me by Sir James Paget. Had suffered for five weeks. Galvanised eleven times. Was greatly relieved, but not cured. Had suffered from uterine displacement, and had been wearing a pessary up to the time of the commencement of the treatment for sciatica. This lady had a subsequent attack of sciatica, and was again relieved by galvanism after trying many other remedies.

CASE 2.—Jan. 26th, 1884. M. W——, female, aged thirty-five. An in-patient of the hospital. Had been ill for three months. Was galvanised about ten times. Cured.

CASE 3.—Feb. 11th, 1884. W. C——, male, aged thirty-three. An out-patient. Had been ill six months. Galvanised four times. Cured.

CASE 4.—Feb. 13th, 1884. M. M——, female, aged thirty-eight. An in-patient. Had been ill four months. Galvanised four times. Cured.

CASE 5.—Feb. 22nd, 1884. J. L——, male, aged fifty-eight. An in-patient. Had been ill six weeks. Galvanised five times. No improvement. On examination per rectum, a tumour was felt pressing on the side on which there was sciatica. After death necrosis of the tuber ischii was discovered. This was therefore not an ordinary case of sciatica.

CASE 6.—Feb. 28th, 1884. W. B——, male, aged twenty-four. An out-patient. Had been ill for ten weeks. Galvanised four times. Cured.

CASE 7.—May 12th, 1884. A. C——, male, aged twenty-three. An out-patient. Ill eight months. Galvanised four times. Cured.

CASE 8.—July 11th, 1884. L. W——, female, aged forty-two. An out-patient. First attack. Had been ill three weeks. Galvanised eight times. Cured. (Some of the out-patients do not return to report themselves when they are well. If no note has been made of their improvement we are doubtful as to the result. In several cases mentioned in this list I have had to go by the note last made. If to the effect "much improved," I have considered their ceasing to attend as evidence of being cured.)

CASE 9.—July 22nd, 1884. C. S——, male, aged thirty-one. An in-patient. The sciatic nerve was stretched on account of the man being subject to epileptiform convulsions. The operation was followed by sciatica and suppuration along the course of the nerve. Galvanised once. Improved.

CASE 10.—Aug. 11th, 1884. A. P——, male, aged twenty-three. An out-patient. Had been ill four weeks. After the third application of electricity he was much better. It appears by the register of cases that he was galvanised twenty-five times. He was quite well when I discharged him; how long he had been so I cannot say. Many of the patients continue coming twice a week for as long as they can. They say they feel so much better for the galvanising, and they think that it strengthens their nerves.

CASE 11.—Aug. 11th, 1884. C. H——, male, aged forty-five. An out-patient. Ill seven weeks. Second attack. Galvanised six times. Cured.

CASE 12.—Aug. 15th, 1884. E. C——, female, aged forty-one. An out-patient. Ill four months. Galvanised eleven times. Cured. The galvanising brought on menstruation.

CASE 13.—Sept. 2nd, 1884. Miss E. S——, aged thirty-one. Had had sciatica for two months, which necessitated deferring her wedding. Galvanised four times. Cured.

CASE 14.—Oct. 20th, 1884. J. O——, male, aged twenty-six. An out-patient. Ill five months. Had been in bed six weeks. Only attended once. Returned some few months afterwards (with another patient), and said that the first application of electricity had cured him.

CASE 15.—Oct. 27th, 1884. J. G——, male, aged twenty-nine. An out-patient. First attack. Had been ill five months. Only attended once. Came from Richmond.

CASE 16.—Nov. 16th, 1884. G. B——, a gentleman sent to me by Mr. Alfred Cooper, aged about fifty. Had been in pain for two weeks. Galvanised once. Cured. On the 15th of the following month he had a return of pain. Galvanised twice; cured.

CASE 17.—Nov. 18th, 1884. J. P——, a gentleman sent to me by Mr. Butlin, aged about forty-two. Had had sciatica for five months. Galvanised eight times. Not cured. (See subsequent note.)

CASE 18.—Nov. 21st, 1884. A. J——, male, aged forty-three. An out-patient. Had been ill for twelve months. Galvanised seven times. Cured.

CASE 19.—Nov. 27th, 1884. E. D——, male, aged forty-five. An out-patient. Had been ill two months. Second attack. Only attended once.

CASE 20.—Nov. 27th, 1884. T. N——, male, aged twenty-nine. An out-patient. Had been ill five weeks. First attack. Galvanised eight times. Much improved.

CASE 21.—Nov. 29th, 1884. C. S——, a gentleman, aged

[1] THE LANCET, 1861, vol. ii., p. 336.

about twenty-nine. Had been ill for a few days. Second attack. Galvanised twice. Cured.

CASE 22.—Dec. 2nd, 1884. M. M——, female, aged twenty-seven. An in-patient. Had been ill five months. Was of a hysterical temperament. Treated by statical electricity. Sparks taken from over the course of the sciatic nerve. Application about eight times. Cured.

CASE 23.—Dec. 4th, 1884. A. F——, male, aged thirty-six. An out-patient. Ill seven weeks. First attack. Galvanised fifteen times. Cured.

CASE 24.—Dec. 29th, 1884. J. E——, male, aged fifty-five. An in-patient. Ill eleven weeks. Galvanised several times. Improved.

CASE 25.—Dec. 29th, 1884. G. N——, male, aged thirty-six. An in-patient. Had been ill for two months. Was in Luke ward for six weeks, and treated by electricity. Was not cured. Was made an out-patient on Feb. 9th, 1885. Galvanised fifteen times. Cur. d.

CASE 26.—Jan. 8th, 1885. A. M——, male, aged thirty-four. An out-patient. Sent to the hospital by Dr. de Havilland Hall. Had been ill ten weeks. Galvanised twelve times. Cured.

CASE 27. Jan. 12th, 1885. R. B——, male, aged fifty. An out-patient. Fourth attack of sciatica. Had been ill two months. Galvanised fifteen times. Cured.

CASE 28.—Jan. 21st, 1885. M. C——, female, aged twenty. An in-patient. Had been ill for three months. Was galvanised in the hospital a large number of times. Improved. Was made an out-patient. Galvanised seven times. Cured.

CASE 29.—Feb. 19th, 1885. A. B——, male. An out-patient. Had been ill two weeks. Galvanised twice. Did not attend after the second time. No note as to whether improved or not.

CASE 30.—Feb. 19th, 1885. G. S——, male, aged thirty-four. An out-patient. Had been ill four weeks. Galvanised ten times. Was better.

CASE 31.—Feb. 26th, 1885. J. H——, male. An out-patient. Had been ill seven months. Galvanised fourteen times. Cured.

CASE 32.—May 7th, 1885. L. D——, male, aged twenty-eight. An out-patient. A policeman. Had been ill for six months. Had been an in-patient of the hospital, and had had his sciatic nerve stretched by forcible flexion, with only temporary improvement. Galvanised eight times. Cured.

CASE 33.—May 8th, 1885. E. C——, female, aged forty-nine. An out-patient. Had been ill for nine months. Galvanised four times. Improved. Ceased attending.

CASE 34.—June 4th, 1885. T. A——, male, aged forty-five. An out-patient. Second attack. Started with a sneeze. Had been ill two weeks before applying at the hospital. Has been galvanised twenty times. Was much improved after sixth application. Has now ceased to attend. The last time he came he said he had been free from pain for a week, but felt it slightly on that day.

CASE 35.—June 11th, 1885. G. T——, male, aged twenty-seven. An in-patient. Underwent an operation for fistula in ano, followed by sciatica. Galvanised eight times. Cured.

CASE 36.—June 24th, 1885. A. D——, a gentleman, aged about thirty. Had been ill for three weeks. Galvanised nine times. Once faradised. Cured. (This patient expressed himself as cured when he discontinued treatment; I afterwards heard that he had a return of his pain, which was relieved by a visit to Aix-les-Bains.)

CASE 37.—July 2nd, 1885. J. A——, male, aged fifty-nine. An out-patient. Had been ill a month. Galvanised ten times. Result not stated.

CASE 38.—July 17th, 1885. A. K——, male, aged thirty-six. An in-patient. Had been ill five weeks. Galvanised ten times. Cured.

CASE 39.—July 21st, 1885. M. H——, female, aged sixty. An in-patient. Had been ill two weeks. Was galvanised. This patient was cured of her sciatica, but in the notes of her case the result is credited to the exhibition of chloride of ammonium.

CASE 40.—July 27th, 1885. A. S——, male, aged forty-seven. An out-patient. Had been ill for five weeks. Galvanised twice. Ceased attending. Result not known.

CASE 41.—Aug. 10th, 1885. An American gentleman, aged sixty-five, sent to me by Mr. Savory. Had been in pain about a week. Second attack. The first attack had been cured by Duchenne with galvanism. Galvanised four times. Cured.

CASE 42.—Aug. 13th, 1885. G. E——, male, aged twenty-six. An out-patient. Has been ill for six weeks. Galvanised five times. Cured.

CASE 43.—Aug. 20th, 1885. E. J——, female, aged twenty-nine. An in-patient. Had been ill for two months. Galvanised five times. Cured.

CASE 44.—Aug., 1885. A member of the surgical staff of the hospital. Had suffered from sciatica for about a fortnight. Galvanised once. Cured.

CASE 45.—Sept. 24th, 1885. J. G——, male, aged forty-one. An out-patient. Had been ill for three months. Galvanised once. Did not return. Result uncertain.

CASE 46. Oct. 5th, 1885. E. G——, male, aged seventy. An out-patient. Had been ill for three months. Galvanised twelve times. Improved.

CASE 47.—Oct. 23rd, 1885. M. B——, female, aged thirty-two. Had suffered more or less from double sciatica for two years. Pain in right thigh relieved after six applications of electricity, but it returned again about Christmas-time. Pain in left thigh relieved by four applications.

CASE 48.—Nov. 12th, 1885. M. W——, male, aged thirty-three. An out-patient. Had suffered from sciatica for two years. Galvanised thirteen times. Improved.

CASE 49.—Nov., 1885. A lady, about thirty. Had had sciatica for six weeks. First attack. Galvanised five times. Improved. Left town for the country before she was quite cured.

CASE 50. Nov. 19th, 1885. C. H——, male, aged forty-two. An out-patient. Galvanised seven times. Cured.

CASE 51.—Nov. 30th, 1885. C. W——, male, aged thirty-seven. An out-patient. Had had sciatica for two weeks. Galvanised eight times. Cured.

CASE 52.—Dec. 21st, 1885. J. L——, male, aged forty-two. An out-patient. Had been ill for five months. First attack. Galvanised four times. Result not stated in notes.

CASE 53.—Dec. 22nd, 1885. M. B——, female, aged twenty-eight. Out-patient. Had had sciatica for six months. Confined a month ago. Galvanised four times. Cured. Came twice afterwards for treatment, as she said she felt so much better for the galvanising.

CASE 54.—Jan. 1st, 1886. R. F——, female, aged forty. Sent to me from the General Post Office. Had been ill three months. Galvanised ten times. Cured.

CASE 55.—Feb. 8th, 1886. G. B——, male, aged thirty-six. An out-patient. A fourth attack. Galvanised eleven times. Cured.

CASE 56.—Feb. 25th, 1886. T. T——, male, aged thirty-four. Out-patient. First attack. Had been ill for twelve months. Galvanised twice. Result not stated.

CASE 57.—March 1st, 1886.—A. W——, male, aged forty-five. Out-patient. Had been ill eight months. Galvanised seven times. Cured.

CASE 58. April 1st, 1886. J. N., a gentleman aged sixty-one, with an enlarged prostate (? malignant). Had had pain down the course of the left sciatic nerve for five weeks. Galvanised seven times. Relieved so as to enable him to leave town for the seaside.

CASE 59.—April 8th, 1886. R. G——, male, aged fifty-six. An out-patient. Third attack. Had been ill this time for eleven weeks. Galvanised three times. Improved. Is still attending.[1]

CASE 60.—April 15th, 1886. J. R——, male, aged fifty-three. An out-patient. Had been ill four weeks. Galvanised once. Is to attend again.[1]

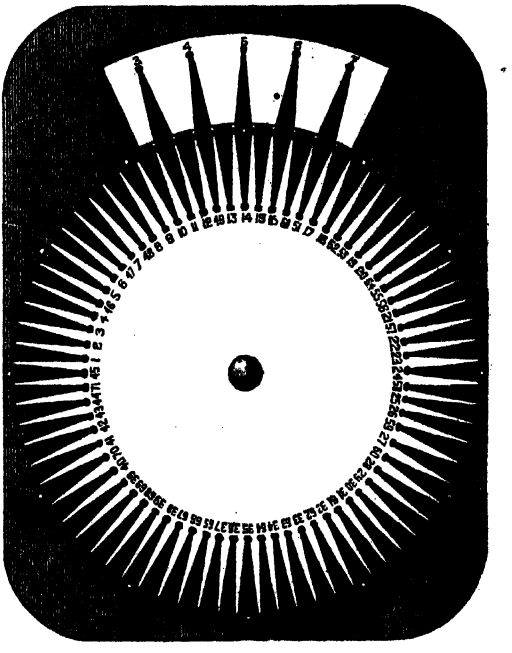
The above sixty cases have been more or less under my care. Thirty-seven have been cured; one had a return of sciatica and was cured a second time; eleven improved only; two did not improve; concerning nine, I am uncertain as to the result; and two are still attending the hospital.[1] Of those that recovered, three cases were cured with one application, two required two applications only, seven cases were galvanised four times each, two were galvanised five times, one case required six times, four cases seven times, five cases eight times, one case nine times, four cases ten times, two cases eleven times, one case twelve times, one case fourteen times, and three patients came fifteen times before they were satisfied that they were cured; one patient escaped my observation, and managed to get one or other of the students to galvanise him twenty-five times before I stopped his coming; he had been free from sciatica for several weeks. Of the cases which were not successful, one patient was, after death, discovered to have extensive necrosis of the ischium, with a sequestrum of dead bone. Another, a lady, was at the time suffering from some malposition of the uterus, which was tilted over on to the side in which the

[1] April 19th, 1886.

pain was felt, and no doubt exercised some pressure on the roots of the nerve. Although in this case the sciatica was not cured, the patient was so much benefited that she was able to get about the house again after eight applications. Before electricity was tried she had been confined to her bed for five weeks. With regard to the second unsuccessful case, I cannot well assign a reason for its non-improvement. The patient was a gentleman who had spent many years in the East Indies, and had suffered from dysentery and ague. He attended and was galvanised eight times, and as he was not then free from pain he did not care to continue the treatment. He tried several remedies afterwards, with the same unsatisfactory result. Perhaps if he had persevered longer with the galvanism he might have been cured, for several of the hospital patients attended as many as ten or fifteen times before they were quite relieved; but there is more difficulty in obtaining the prolonged and regular attendance of a patient who has to pay for each application than of one who gets his treatment gratuitously. The cases included in my list bear out the favourable opinion expressed by Dr. Stone, in his recent Lumleian Lectures, of the action of electricity in the treatment of sciatica.

Welbeck-street, W.

A COLOUR CIRCLE FOR TESTING THE CHROMATIC SENSE.



By C. S. JEAFFRESON, F.R.C.S.E.,

SURGEON TO THE NORTHUMBERLAND, DURHAM, AND NEWCASTLE INFIRMARY FOR DISEASES OF THE EYE.

EVERY instrument which tends to simplify and render more easy the functional examination of the eye is a great boon to the ophthalmic surgeon, not only by enabling him to do his work with less fatigue, but by facilitating the conduct of inquiries upon a much larger scale than is possible when the means at his command necessitate complicated apparatus or a lengthy system of examination. These remarks specially apply to the perception of colours. Within recent years defects in the colour sense, whether congenital or acquired, have assumed an importance which can scarcely be over-estimated: the former chiefly in connexion with the recognition of lights and flags in the railway and marine services; the latter in connexion with the different forms of amblyopia dependent upon diseases of the optic nerves and the various parts of the brain which constitute the visual centres.

It is not my purpose here to discuss the various theories which have been advanced in explanation of the phenomena of colour perception, but to introduce to the notice of the profession a piece of apparatus which I have had constructed with a view to the rapid detection of errors in this direction. Most of the methods in general use are either too complicated or not sufficiently efficient. Holmgren's is, of all others, perhaps the most convenient, but, carried out with the detached skeins of wool, it is tedious in its application and requires a good deal of talking and explanation. The wools, too, require constantly remixing; they are apt to be thrown about or mislaid; and, withal, there is no ready method of keeping a record of the colours that have been erroneously selected by those who have a defective chromatic sense. This system therefore is ill-adapted for the out-patient department of a hospital. What is required is some instrument which, always at hand, can be rapidly and efficiently applied with the minimum loss of time, and these attributes I claim for my instrument. The principle is essentially that of Holmgren, but the application is somewhat modified for the sake of rapidity and convenience.

The instrument consists of a test board and a revolving colour disc. The disc consists of a white enamel tin plate twenty-two inches in diameter. Its margin is cut out or notched so as to form together 72 bobbins or winders to hold the skeins of different colours. The wool, when placed upon these winders, passes through an aperture which is situated opposite the centre of each notch; it thus assumes the form of a cone, the apex of which is directed towards the centre of the circle, the base occupying the extreme margin, as clearly seen in the annexed sketch, where the shaded cones represent the colours. The test board, which is fixed and immovable, consists of a segment of a circle, also enamelled, so placed that its concavity exactly fits the convexity of the disc. Winders to hold the test colours are let into this tin plate in the same way as upon the disc, but the bases of the cones are directed towards the concavity of the test-board, the apex outwards. In this way the base of any colour cone on the wheel can be placed in exact apposition with the base of any colour cone upon the test board, forming with it a figure of this form: $\frac{\Delta}{\nabla}$. The disc rotates upon its centre, and by means of a weak catch stops when the bases of the cones are exactly opposite the bases of the cones on the test board. The colours that have been selected for the test board are the colours of the spectrum: red, orange (yellow), green, blue, and violet; and purple has been added, with a view to enable the tests to be applied upon Holmgren's principle. The green is the pale green which represents his No. 1 test; the purple is the tint which represents his test No. 2; the red is the full red which represents his test No. 3; the blue is a pure saturated blue, neither inclining to red nor green; the violet is a pure violet, as near to spectral violet as can be obtained. These test colours are arranged upon the board and numbered

as follows (there is no No. 1 or No. 2, for reasons which will follow): No. 3, pale green; No. 4, purple; No. 5 red; No. 6, blue; No. 7, orange or yellow; No. 8, violet. Upon the circle there are in all 72 colours, and they are numbered as follows: 1 to 19 represent the lighter shades of confusion colours; 20 to 29 the darker greys and browns; 30 to 36, greens of various shades; 40 to 46, purples of various shades; 50 to 56, reds of various shades; 60 to 66, blues; 70 to 76, yellows and oranges; 80 to 86, violets. To scatter the colours and yet to preserve some kind of order, the numbers do not follow each other consecutively on the circle, but in the following order: 1, 10, 20, 30, 40, 50, 60, 70, 80[1] (which represent one of each of the series of colours); then Nos. 2, 11, 21, 31, 41, 51, 61, 71, 81 (which represent another series), and so on in succession; each series as much as possible representing darker shades as they progress towards the higher numbers. In this way no two colours of the same hue come together upon the circle, and they appear generally scattered, although really a definite order is preserved. Now, with this arrangement it is easy to register and keep a record of the colour defects a person who is

[1] By a mistake of the engraver the numbers are erroneously placed on the block.

examined may show; so that we may, as it were, subsequently examine him without his presence and study carefully his defects.

Let us now explain how the circle is used. A test colour (whichever is desired) is shown to the patient, and he is directed to look at it carefully, and then gradually and slowly turn the wheel until a colour which to his eye corresponds, although of a lighter or darker shade, comes immediately above it, and completes the figure which is formed by the junction of the two cones at their bases. When he is convinced of the correspondence, *he is to remove his hand completely from the wheel*, and the examiner then notes the number of the colour chosen. Now, in recording the cases, if we write down the number of the test as a numerator and the numbers of the colours chosen as denominators, we shall find that, in accordance with the arrangement of the colours and their numbering, in a person with normal chromatic sense, the first number of the denominator will always be the number of the numerator, because the different shades of each colour are grouped in series of tens—the greens are all under 30, the purples under 40, the reds under 50, and so on, their corresponding test number being 3 for green, 4 for purple, 5 for red, and so on.

Let me give a few practical illustrations. A patient presents himself. Test 3 (the pale green) is given him. He stops the wheel only at 30, 31, 32, 33. C. S. = $\frac{3}{30 \cdot 31 \cdot 32 \cdot 33}$. In other words, his colour sense is normal. Another patient presents himself. No. 3 is given to test. He selects 1, 5, 7, 6 (confusion colours). C. S. = $\frac{3}{1 \cdot 5 \cdot 7 \cdot 6}$. He must therefore have dyschromatopsia. Has he partial achromatopsia? No. 4 is now given him to sort (purple). He stops the wheel only at the series of 40—$\frac{4}{41 \cdot 43 \cdot 44}$. He has no partial achromatopsia. Had he stopped the wheel at 60 (blue) or 80 (violet), his colour sense would have been recorded $\frac{4}{41 \cdot 43 \cdot 60 \cdot 80}$, and he would have been suffering from red-blindness, according to the Young-Helmholtz theory. Had he selected with Test 4 any of the series of 30 (greens), or any of the darker greys contained between 19 and 29, he would have been green-blind, according to the same theory, and his case might be thus recorded: $\frac{4}{40 \cdot 30 \cdot 24 \cdot 27}$.

I need not multiply these illustrations, as far as the other tests are concerned. Anyone who is acquainted with Holmgren's system will see how they can be applied and recorded according to the plan I have laid down. A glance at the diagram will render easy of comprehension the somewhat complicated verbal description which has been found necessary. The instrument has been carefully and elegantly prepared by Messrs. Picard and Curry, the well-known opticians, of Great Portland-street, London. It works smoothly and well, and should, I think, find a place in the consulting-rooms of both the physician and ophthalmic surgeon, railway offices, recruiting depôts, private and public schools, and other places where the testing of the colour sense is a question of interest.

It has been urged as one of the chief features of Holmgren's system that the hand and eye combine together to reveal the defect of colour sense in patients who are submitted to this form of examination; the hesitancy and vacillation of their movements in selecting the skeins giving a clue to the deficiencies of their perceptive colour functions. In using the colour circle these manœuvres between the eye and the hand lose nothing; I think, indeed, they become more conspicuous, and frequently enable us to detect a colour-blind person at a glance. A person with normal chromatic vision, who has had the operation of the wheel explained to him, will sit down and go through the various tests in less than a minute. A colour-blind person seems to shrink from the wheel; when he sits down to it he turns it with hesitation, and in a few seconds usually convicts himself. There may be a difficulty sometimes with stupid persons, as there are in all forms of examination; but we must beware of those who *pretend to be stupid*, and who, in reality, are deficient as regards their colour perceptions, but hope to escape by leaving the examiner under the impression that they are lacking in intelligence. The examiner should not lose patience with this class, but should carefully explain what is wanted of them, and should himself go through the tests with the wheel. A person who is stupid only will at once see what is required, whilst one who is colour-blind will receive no assistance by seeing the examiner sort the colours.

Newcastle-on-Tyne.

A CASE OF SENSORY APHASIA,

WITH NECROPSY.

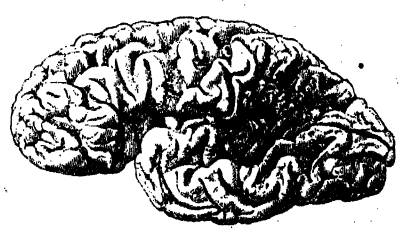
By JOSEPH WIGLESWORTH, M.D. Lond.,
ASSISTANT MEDICAL OFFICER TO THE RAINHILL ASYLUM.

I AM indebted to Dr. Rogers for permission to publish an account of the following case.

Mary C—— was admitted into Rainhill Asylum on March 28th, 1885. No particulars were known about her, and it was never possible to obtain any information, for nothing could be ascertained about her friends, and the patient herself was unable to assist us. She was a grey-haired old woman, a little above middle height, and appeared to be about sixty-five years of age. Her irides were grey; the right pupil 3 mm., the left 2½ mm.; both acted well to light and to accommodation. The tongue was protruded straight, but showed considerable fibrillar tremor. There were slight signs of pulmonary emphysema, expiration being a little prolonged and wheezy. There was evidence of cardiac hypertrophy; the cardiac dulness was a little increased to the left, the apex beating in the fifth space in the nipple line, and there was a well-marked systolic bruit at the apex, heard with almost equal distinctness at the base; the aortic second sound was loud. The arteries generally were abnormally distinct. The urine contained the merest trace of albumen, but no sugar. No paralysis of any kind.

Mental condition.—She was, when admitted, very quiet, scarcely attempting to speak except when addressed; when a conversation was opened with her, however, she disclosed great amnesic defect. She gave her name as "Mary," but could not get any further, and, in fact, answered "Mary" to a number of quite unrelated questions. When shown various common objects, such as keys, a knife, &c., she could not name one of them, nor could she be got to repeat the names told her, except in one instance; she did not, indeed, seem to recognise the objects, nor could she be got to indicate, by gesture or otherwise, their use. To many questions she answered "Yes" quite irrelevantly. She could, however, talk pretty fluently when left to herself, though it was impossible to get anything connected out of her, as she constantly was at a loss for words, or misplaced them, and frequently repeated sentences or parts of sentences over and over again. She could, nevertheless, generally give some indication of what she wanted. She could not write, but seemed to try to make it understood that her failure was due to her right hand being numb; she had, however, free use of it. She appeared to ascertain extent conscious of her defect, for frequently, when asked the name of anything, she said, "I cannot speak it"; but the impression conveyed was that she was only partially aware of her failings, and that there was some intellectual defect beyond her mere incapacity for naming objects. She clearly did not understand many things that were said to her. She frequently showed some amount of emotional excitement when unable to say what she wished.

About two months after admission—viz., on May 23rd—the patient had three epileptiform fits. On June 27th the following note was taken: "Mental condition much the same; she sits still most of the day very quiet, without speaking, unemployed; occasionally talks a little to herself. She has some command of words, but cannot apply them properly, and her conversation becomes, in consequence, ludicrously incoherent. She cannot name any object shown her, though she clearly recognises these at times, and assents when the proper name is given her; she is, however, *just as often wrong as right*. She also has a certain perception of her own defect, for she says she knows what a thing is if she could only name it, and shows some emotional excitability at her repeated failures. She clearly understands many things said to her, for she puts out her tongue and shuts her eyes when told to do so; says 'Good morning' appropriately. There appears to be some general intellectual feebleness, in addition to the amnesia."



After this date the patient got very restless. She would

come forward spontaneously every morning on the medical visit and endeavour to tell a long story about herself, trying to make up for her defect of speech by the use of gesture. She was, however, never able to express her meaning, though she frequently seemed to wish to make some complaint of her bodily condition; she always seemed very agitated, and became very depressed at her repeated failures. This continued more or less for a few months, and she then gradually became quiet, seeming to get more reconciled. On Oct. 18th she had another epileptiform fit; this was not repeated.

On March 4th, 1886, the patient's condition was noted to be as follows: "She is much quieter and less obtrusive than formerly, which may possibly be due to the fact that she has found out how impossible it is for her to make herself understood. She can say numerous words and sentences, but what she says is almost all irrelevant and incoherent, although not completely so. She seems quite destitute of the power of naming, and is unable to recognise the names of objects, even when these are given her, although this inability is not quite complete. She gives her name as 'Mary,' but cannot be got to give her surname, saying, 'I cannot speak it'; this is, indeed, a favourite expression. Shown a knife and asked what it is, she says, 'I know the price of it,' but she cannot give the name; and when various names are suggested, dissents from most of them, but agrees both when 'key' and 'knife' are suggested. Shown a pocket-book, she cannot name it; and when asked if it is a book, says 'No,' as she does when other names are suggested, but shows that she understands the use of it by opening it and pretending to write in it with her finger. Shown a prayer-book, she opens it and looks as if she understood it, but when asked what it is she cannot say in the least; and when 'knife' is suggested, assents; but afterwards, having opened it at the Psalms, says spontaneously, 'This is the Psalms'; on being asked to read it she makes signs for glasses, which are given her, and she appears quite able to see the print, but cannot read a word, and says, 'If I could speak it, I could say it.' Given a pencil and paper and asked to write down the words, she cannot make a stroke, even when the letters are dictated to her. The plantar and abdominal reflexes are well marked, as also the knee-jerks. Sensation appears good everywhere. Right pupil 3½ mm.; left, 3 mm., the latter slightly irregular; both act to light and to accommodation, but are sluggish. Attempts were made to test the patient's vision for hemiopia &c., but no reliable results were obtained. Tongue protruded straight; steady as a whole, but shows great fibrillar tremor."

On the morning of April 12th the patient died very suddenly and unexpectedly. She had just dressed herself, and was sitting on the side of the bed, when she suddenly fell back unconscious; she became pale and frothed at the mouth, but no convulsions were recognised; she died in a quarter of an hour.

Necropsy, seven hours after death.—Skull-cap a trifle thick. Dura mater somewhat abnormally adherent anteriorly. Longitudinal sinus empty; about three ounces of fluid in subdural space. Arachnoid generally very white and opaque; it and pia mater decidedly thickened; everywhere strip readily; no adhesions. Moderate general wasting of gyri, with corresponding excess of subarachnoid fluid. On the outer surface of the left hemisphere, occupying the region of the inferior parietal lobule, was a deep depression caused by the destruction and absorption of the convolutions here situated. The depression was bounded above by the intra-parietal sulcus, below by the posterior half of the parallel sulcus, in front mainly by the lower part of the ascending parietal gyrus, and behind by the occipital lobe. The convolutions implicated were the supra-marginal, the angular, and the posterior half of the superior temporo-sphenoidal. The angular gyrus had disappeared in its anterior three-fourths, the posterior fourth remaining attached to the occipital lobe; the posterior three-fourths, or rather more, of the supra-marginal gyrus, was also destroyed, a small portion of the anterior part, where it joined the ascending parietal gyrus, being intact. The same destruction had overtaken the posterior half of the superior temporo-sphenoidal gyrus. The destruction of brain tissue here was complete, and was not confined to the outer aspect of the convolutions, but extended into the white matter almost down to the lateral ventricle; at the posterior end of the ventricle, indeed, over an irregularly circular area about the size of a florin, there was only a layer, not more than a line in thickness, of disorganised brain substance, between the inner surface of the ventricle and the outer surface of the cerebrum. This destruction of brain tissue appeared to have been due to a process of necrotic softening and subsequent absorption, doubtless from the cutting off of the blood-supply by the plugging of the vessel supplying the area in question. The destroyed area corresponded pretty accurately with the region of distribution of the parieto-sphenoidal branch of the middle cerebral artery. The convolutions of the motor area were absolutely intact, as indeed were all the remainder, both in this hemisphere and the right. Left ventricle considerably dilated, right moderately so. Cortex of normal pale grey tint, of average depth, and lamination distinct. Consistence of brain good. Basal ganglia normal, as also cerebellum, pons, and medulla. The brain (immediately after removal) weighed 1169 grms.; right hemisphere, 476 grms.; left hemisphere, 403 grms. (both stripped of membranes); cerebellum, 123 grms. Numerous atheromatous patches on basal vessels and main branches. The heart weighed 11½ oz., and showed distinct hypertrophy of left ventricle; valves competent; slight thickening of base of aortic valves, and of anterior flap of mitral. Moderate atheroma of lower portion of aorta, and this vessel slightly dilated. Lungs moderately emphysematous, but otherwise normal. Liver

Lateral surface (left). The shaded portion indicates the area destroyed. (This figure is from a photograph kindly taken for me by Mr. F. T. Paul.)

and spleen normal. Kidneys each weighed 5½ oz. Capsules somewhat adherent, leaving a distinctly granular surface on stripping. Cortex of right fairly normal; that of left somewhat diminished in depth, and in places fatty; in the centre was a distinct cicatrical depression.

Remarks.—The case before us presents us with an example of disorder of speech due to lesion of the perceptive sensory centres in which spoken and written speech are elaborated; the motor centres, or those which preside over the expressive part of the process of speech, being intact. The case, indeed, is an example of combined *word-blindness* and *word-deafness*. That the above-mentioned sensory centres should simply be a part of the general cortical centres for sight and hearing is what we might have anticipated, and numerous cases have been recorded in which the subjects of this form of aphasia have exhibited after death a lesion in the same situation as in the case here described—viz., in the inferior parietal lobule and posterior part of the first temporo-sphenoidal gyrus on the left side. In the case under consideration the destruction did not involve quite the whole of this area, which may perhaps account for the fact that the patient's defect was not absolute; but I think it equally probable that the corresponding centres in the opposite hemisphere might have been able to furnish some assistance.

THE BOARDING-OUT OF PAUPER CHILDREN.—The plan of boarding-out children belonging to the workhouse has for the past twenty years been tried in the Cork Union, and with very satisfactory results, as shown by the annual inspection of the children last week. The movement originated in consequence of an inquiry which was held in 1862 at the instigation of Sir John Arnott, relative to the great mortality in the workhouse of orphan and deserted children. The guardians pay a monthly sum of 12*s.* 2*d.* for the rearing of each child. During the past twenty-four years about 1000 children have been sent out to nurse, and the results must be regarded as encouraging, as during that long period not more than twenty of the whole number died. When the children arrive at the age of thirteen they are generally adopted by their foster-parents, and in this way avoid the contaminating influence of the workhouse.

CASE OF PARTIAL HYSTERECTOMY FOR FIBRO-MYOMA.

BY JAMES BRAITHWAITE, M.D.,
OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY.

IN a case of large and rapidly growing fibroid uterus, attended with such hæmorrhage as to endanger life, only two courses are open, if the patient is not to be left to her fate—viz., (1) to remove the uterine appendages, or (2) to remove the uterus as a whole, except the cervix, which forms the pedicle. I believe, however, that it has never hitherto been pointed out that if neither of these plans is available there is still open a third mode of operating, one which may at first sight appear to be, and possibly is, more hazardous than either, but which, nevertheless, avoids the principal dangers peculiar respectively to either oöphorectomy or hysterectomy as ordinarily performed. Apart from septicæmia, the principal danger of removal of the uterine appendages (for oöphorectomy, strictly speaking, is not the operation proper to these cases) is secondary hæmorrhage. One main source of danger in hysterectomy arises from retraction of the pedicle. Both these dangers were avoided by the mode of operating adopted in the following case—*how*, I will explain in its relation.

I will not go through the details of the history and diagnosis of the case, but will state briefly that the uterus was a mass of fibroids, reaching nearly to the under surface of the liver. It was still growing, although the patient was forty-nine years of age, and she was drained by hæmorrhage and wearied with constant pain. On January 26th last I made an exploratory incision with the view of seeing whether removal of the tumour were possible, or, if not, with the object of removing the uterine appendages. Mr. McGill and Mr. Robson of Leeds, and Drs. Black and Lever of Harrogate, were present. After making the abdominal wall incision, it was found that hysterectomy as ordinarily performed was impracticable, because there was no narrow part to form a pedicle, for the cervix was distended with fibroid growths to a large size, and it was impossible to raise the uterus upwards from the pelvis owing to its being held down by thick and firm but short broad ligaments. On the other hand, removal of the uterine appendages, though easy on the right side—and, indeed, I did remove a large hydro-salpinx,—on the left side would have been extremely hazardous, as the ovary was embedded in the side of the tumour, had no pedicle, and was entirely covered with large thin-walled veins. Thinking it better for the patient to die a natural death than from intra-peritoneal hæmorrhage within twenty-four hours, and death from natural causes appearing less probable than death from the operation, if proceeded with, I returned the tumour into the body, intending to close the wound. At this point my colleagues and friends forsook me, thinking all was over. As soon, however, as the tumour was replaced, blood welled up in large quantity, and its source could not be discovered; the tumour was therefore again raised and examined, as it was more than once, because the hæmorrhage ceased when the tumour was raised. The ligature was safely on the place whence the tube had been removed, and the bleeding did not come from this source. I therefore for a moment found myself in a difficulty from which no means of extrication could be seen. Not attempting any traction, I simply flexed the uterus forwards out of the wound, applied a Lawson Tait's clamp wire, and removed it by cutting through the body at a spot which seemed the most favourable, and where it was about four inches in diameter. When the clamp was tightened up this was reduced to a diameter of about two inches and a half. On bringing the wound together round the pedicle, it rested on all sides upon the mass beneath, which was as large as a uterus at five months' gestation. By weight, I suppose that two-thirds of the tumour would be removed, and one-third left behind. The uterine cavity was cut through in removing the tumour, and of course both ovaries went with it. Hæmorrhage from the stump occurred several times, but it was controlled, and the patient made an excellent recovery, thanks in great measure to the assiduous care of the resident obstetric officer to the infirmary, Mr. Croft.

It seemed to me that the successful issue of this case depended a great deal upon what might be considered the very fault of the operation—viz., the large size of the mass left behind. As stated, the edges of the wound rested upon this mass all round and adhered to it, so shutting off the peritoneal cavity. For the same reason there was no traction upon the pedicle—indeed, it never retracted, it was too large, and consequently all danger from this source was avoided. The mass left behind did no harm; it ceased to grow, and to some extent has shrunk. It now forms part of the abdominal wall, and has upon its surface a small fibroid, which has appeared since the operation, although the base from which it grows is smaller.

Leeds.

NOTES OF A FATAL CASE OF

POISONING BY BISULPHIDE OF CARBON;

WITH POST-MORTEM APPEARANCES AND REMARKS.

BY WM. FOREMAN, L.R.C.P. & L.R.C.S. ED.

POISONING by bisulphide of carbon is so rare that the following notes of a case may be deemed of some interest.

On March 15th of the present year, I was called at 5.30 P.M., to J. S——, aged sixty-three, shoemaker. He had been drinking for the previous ten days, and had come in from the public-house at 4.30 P.M., and asked that some gin should be sent for; this was done, and almost immediately afterwards he was noticed to be strange, and said, "I have done it." It was then perceived by a bottle close to him and by the smell that he had swallowed a preparation used by him in his trade, and which turned out to be bisulphide of carbon. I was at once summoned, and probably a quarter of an hour elapsed between his taking the poison and my seeing him. When I saw him he was sensible, and wanting to go in the back yard to defecate, but the persons present were trying to keep him in his chair. I was not able to get any information from him. There was a very strong smell of bisulphide of carbon in the room. I at once administered a tablespoonful of mustard with six ounces of warm water. He drank about four ounces. I then left him, and prescribed forty grains of sulphate of zinc, to be taken at once in warm water if the mustard had not acted; afterwards to take fifteen grains each of bicarbonate of soda and carbonate of magnesia every ten minutes. At 6.15 P.M. I saw him again, at which time he was completely unconscious, and could not be roused. As he had not vomited, I introduced the stomach-pump, but only obtained a small quantity of brown-coloured fluid, with a white frothy substance floating on the top, due probably to the mixture of soda and magnesia which had been given. I washed out the stomach with warm water. The pupils were normal, but reacted to light; conjunctivæ suffused and insensible to the touch. Respiration slow, long, and stertorous; pulse small, rapid and compressible, varying from 150 to 160 a minute. Surface of the body cold and clammy; tongue thick and furred. After washing out the stomach, I gave him two tablespoonfuls of brandy in half a glass of water through the stomach-pump. He never rallied, but died about two hours and a quarter after taking the poison.

Through the kindness of our coroner, Mr. Rowbottom, my partner, Mr. Berry, received instructions to make a post-mortem examination, which was made conjointly twenty hours after death, when the following appearances were noted:—Rigor mortis complete; pupils normal; hypostatic congestion of dorsum; body well nourished. On opening the head, the dura mater was adherent to the calvaria; surface of the brain much congested; veins gorged with black blood. Brain substance healthy. Thorax: The left lung was slightly adherent at the apex; no effusion in the pleural cavities; lungs healthy. Heart: The right ventricle contained about an ounce of dark fluid blood; walls covered externally with a layer of fat; left ventricle firmly contracted and empty. Abdomen: The stomach contained about a quarter of a pint of fluid, with flakes of lymph in it, slightly ropy, and appeared to be water and mucus. A faint smell of bisulphide of carbon was perceptible. The submucous tissue was injected, and there was a number of minute hæmorrhages. The posterior wall of the stomach was much more congested (to the size of a crown-piece) than the anterior surface. There was no perforation or

ssion of mucous membrane. The spleen was small, but lthy. The liver was normal in size, and healthy. The eys were surrounded with a large quantity of fat; they slightly congested, but healthy. The bladder contained out two ounces of urine, having a slight smell of bisul- ide of carbon. There was less of the cadaveric smell than usual in post-mortem cases.

Remarks.—Bisulphide of carbon would appear to be a rcotic poison and very powerful in its action. In this se, although I had difficulty in ascertaining the quantity, lf an ounce would be the full amount taken. In the *edical Times and Gazette* of 1878 (vol. ii., p. 350) I find ase reported with symptoms similar to the foregoing, but ith a better termination, as the patient recovered after ing comatose for some hours. In that case two ounces is id to have been taken. In my case the patient became coma- se in half an hour and could not be roused, and, although e stomach was emptied, no abatement of symptoms curred and death took place in two hours and a quarter.

Wigan.

ON A CASE OF CÆSAREAN SECTION.

By JOSEPH HARPER, L.R.C.P. LOND., &c.

rs. G——, twenty-seven years of age, straw-plaiter, rried, primipara, a very small woman, 5 ft. high, weighing lb., living in a small, close, ill-ventilated house over a undry in Barnstaple, engaged my partner, Mr. Henry ckson, to attend her in her approaching confinement. She as taken ill about 5 A.M. on Dec. 1st, 1885; the pains were ght, and not enough to keep her awake for any time; out 10 A.M. they were worse, and came on regularly at .M. She then sent for Mr. Jackson, who, on his arrival, ound the patient dressed and downstairs. He gave some neral directions, did not make any vaginal examination, d told the nurse to send for him when he was wanted. he liquor amnii escaped at 5 P.M. He arrived at the house 6 P.M., and, on making an examination, found the os fully ilated and the head and right arm presenting. The head uld be felt at the brim of the pelvis. He tried to turn, but iled to do so. He then sent for me, requesting me to bring loroform. I went, and found the presentation as described. loroform was administered, and when fully under its fluence I tried to push up the arm of the child, but was able to do so. I then tried to turn, but failed. After veral attempts Mr. Jackson again tried, but without suc- ss. The hand could be got up as far as the chest of the ild, but the difficulty seemed in the outlet of the pelvis, or it was impossible to get the arm further up the passage. The cord now became prolapsed, and, as it was not pulsating, determined to perforate and try to deliver with the otchet. After perforating, I introduced the crotchet into e skull and brought the head well into the brim of the elvis, but was unable to deliver. We then decided to ask r. Cooke to come and give us his assistance. He tried to rn, but met with the same difficulty as we had done, d with the same result. He then tried with the crotchet; t after repeated unsuccessful trials, the external parts eing swollen and hot, our patient having been under loroform for three hours, we reluctantly came to the nclusion that Cæsarean section was the only chance r her.

The necessary preparations having been made, and chlo- oform administered by Mr. Jackson, I washed my hands d the surface of the abdomen with a strong solution of rbolic acid, and the instruments and sponges were mersed in carbolic solution. A catheter was then passed d the bladder emptied. I made an incision in the linea alba om just below the umbilicus to within a couple of inches of e pubes; but finding the incision too small had to extend it the right about an inch above the umbilicus. After making cision into the cavity of the abdomen, Mr. Cooke kept ound on the stretch with his two forefingers, and the supported the sides of the abdomen and kept the well forward. There was very little hæmorrhage. he empty bladder was visible just above the pubes. I then ade an incision of about four inches in the wall of the uterus, hich appeared thin and pale and came down upon the hild covered with the membranes. There was no hæmor- rhage, but the edges of the wound appeared to retract. I removed the body of the child with ease, but the head, from having been pulled down into the brim of the pelvis, required some force for its extraction. The placenta, which was at the back and lower part of the uterus with the membranes, came away with the child, a male, weighing 6¼ lb. There was a copious hæmor- rhage from the interior of the uterus and also from the sinuses of the uterine walls, which I checked by pressing with my hand, but which recurred directly I let go. Mr. Cooke now kept the edges of the wound together for me, and I introduced a silver wire suture, with the effect of checking the hæmorrhage, and the uterus contracted under a little pressure. The cavity of the abdomen was washed with warm carbolic solution, the omentum replaced, and the edges of the abdominal wound brought together with silver wire sutures. Iodoform was sprinkled over the wound and covered with a piece of lint soaked in carbolic oil, a pad of lint being placed on either side of the wound. Gauze, cotton-wool, and a binder were applied, and the patient removed to bed, which had been properly prepared for her. A hypodermic injection of morphia was given, and she was left tolerably comfortable. Pulse 136; respiration 28; temperature 99°.

Dec. 2nd.—11.45 A.M.: Has been very comfortable all night, dozing most of the time. Pulse 120; respiration 22; temperature 99·4°. Four minims of morphia injected; catheter passed. — 9.30 P.M.: Complains of pain in right iliac region; lochia natural in colour and quantity. Pulse 126; respiration 26; temperature 99·6°. Catheter used and morphia injection repeated. No sickness.

3rd.—11 A.M.: Has had fair sleep; no sickness; has taken milk, egg, brandy-and-water, and ice; lochia scanty, but of good colour. The vagina to be washed out with weak solution of Condy's fluid twice a day. Pulse 112; respiration 26; temperature 100°.—9.40 P.M.: Has vomited twice to- day; complains of flatulence. Pulse 100; respiration 30; temperature 99·4°. Catheter introduced; morphia injection repeated.

4th.—11 A.M.: Has slept fairly well, but is rather restless and thirsty; has been sick several times. Pulse 110; respira- tion 30; temperature 100·4°. Introduced catheter; injection repeated. Takes milk, beef-tea, brandy-and-water, and ice. Pain in side less, and feels comfortable.—8.30 P.M.: Pulse 112; respiration 30; temperature 99°. Introduced catheter; injection repeated.

5th.—11 A.M.: Has passed urine freely; bowels acted once; several clots have come away; taken very little food. Pulse 110; respiration 28; temperature 98·8°. Injection repeated.

6th.—Has slept well during early part of night; feels comfortable; takes more food; no sickness, but has pain on each side of the bowels. Pulse 104; respiration 24; tem- perature 100·6°. Injection repeated.—9 P.M.: Passed a fair day; pain in sides slightly increased; inclined to be ex- cited; complains of swelling and irritation of throat. Pulse 100; respiration 24; temperature 100·6°. Injection repeated.

7th.—11 A.M.: Has passed a good night. Pulse 104; respiration 30; temperature 100°. Injection repeated.— 10 P.M.: Ordered an enema, which gave great relief and brought away a large quantity of fæces.

8th.—Slept well; complains of pain in left side: slight fulness. Pulse 98; respiration 26; temperature 99·4°. In- jection repeated.—9.30 P.M.: Injection repeated.

9th.—Removed the sutures; abdominal wound healed; has had a good night; slept well; no sickness; bowels moved once naturally; vaginal discharge very little, but rather offensive. Pulse 100; respiration 26; temperature 100·4°. Omitted the morphia.—8 P.M.: Pulse 100; respira- tion 28; temperature 99·8°.

10th.—11 A.M.: bowels have acted freely twice; has had some good sleep; no sickness; no pain in breasts, nor has any milk been secreted; lochia pale, and still offensive. Pulse 92; respiration 24; temperature 98·4°.

She progressed well until the 13th, when she had a copious discharge of bright-red blood. Quinine, iron, and extract of ergot were given. From this time she progressed rapidly, and on the 26th a belt was applied. She came downstairs on the 29th. For ten days prior to the 30th, Mr. Jackson tells me, the pulse, temperature, and respiration had been normal. On Feb. 26th it was stated that she had remained well, with the exception of slight dyspepsia, but had not yet menstruated.

Barnstaple.

CASE OF

CÆSAREAN SECTION AFTER PROLONGED LABOUR IN CONTRACTED PELVIS AND HYDROCEPHALIC (?) FŒTUS.

BY C. D'A. COLLINGS, M.A., M.B. OXON.

THE following case may be of interest to the readers of THE LANCET.

On the evening of Dec. 31st I was summoned to see Mrs. W——, as the midwife in attendance found that the labour did not progress. The patient was an ordinary-sized woman, a primipara, forty-three years of age. She estimated her pregnancy to have lasted ten months, and said that she had felt no fœtal movements for about a month; that she had had some indefinite abdominal pains for some time; but reckoned her labour pains to have begun on the previous Sunday (Dec. 27th), since which day she had taken scarcely any nourishment and had had no sleep. The liquor amnii was thought to have come away on the morning of Dec. 31st. On examination, a smooth, rather tense sac was found presenting in the upper part of the vagina, feeling like the bag of membranes, but becoming only slightly less tense during the intervals of the pains; and on passing the finger round in search of the margin of the os, this could not be felt, but small collections of hair were found apparently adhering loosely to the sac, as some of it was easily extracted for examination. The appearance of the sac as seen when the walls of the vagina were separated and a light cast up, was smooth, slate-coloured, and somewhat shining. A puncture with a grooved needle gave exit to a drop or two of semi-liquid matter of a sanguineo-purulent appearance. The bones of the fœtal head could not be felt on pressing the sac. The patient's pulse was 120 per minute. A bruit synchronous with it was heard over the abdomen to the left of the umbilicus, both above and below, but not to the right; the right side of the abdomen was rounder and fuller, as if the back of the child lay on this side.

As the presenting part was taken to be an encephalocele or a hydrocephalic head, Dr. Le Page was called in consultation, and it was decided to open the tumour, as no progress was made with the labour, and it was found impossible to push the tumour up or get the hand into the uterus to turn. The tumour was opened with a lancet, and a quantity of semi-fluid brain matter mixed with blood escaped, having the general appearance of the central softening in a case of tubercular meningitis. The thin parietal bones were then felt movable within the sac, and the base of the skull was felt just above the brim. The pelvic brim appeared to be equally contracted (justo-minor), and the hand could be inserted only with difficulty into the uterine cavity, the walls of which remained firmly contracted; and after several attempts under chloroform, it was found impossible to reach the feet to perform version, and on each withdrawal of the hand the presentation was found to have returned to a shoulder, and one of the fœtal arms appeared in the vagina. Fearing that further attempts at version might injure the uterus, it being so firmly contracted and the liquor amnii having so long been drained away, it was decided to draw down the arms in turn and amputate them at the shoulder-joint, in the hope that with the diminished width of shoulder the head and body might be drawn down with the craniotomy forceps or the cephalotribe. The amputation was easily accomplished with a curved blunt-pointed bistoury, each arm being drawn down in turn and disarticulated at the shoulder-joint; it was, however, still found impossible to get an instrument beside the hand through the brim, so as to decapitate or get hold of the base of the skull, which was fixed above the symphysis pubis. As the abdominal section appeared to be now the only means of delivery, it was decided to desist from further attempts for a few hours, in faint hope that natural efforts might fix the remains of the head in the pelvic brim. The patient was left between 2 and 3 A.M., with instructions for her being conveyed to the hospital early in the morning. When seen in the morning the swelling of the soft parts had further obstructed the pelvic canal, so that the hand was inserted with difficulty; the presenting part was found to be the amputated left shoulder. Drs. Carey and Robinson having been called in for further consultation, and an ineffectual attempt at evisceration having been made by passing the perforator into the scapular region, it was decided to proceed to t Cæsarean section without further delay.

The patient therefore, being kept under chloroform and ether, the abdomen was pressed inwards towards the middle line, so as to shut off as much as possible the peritoneal cavity and prevent protrusion of the intestines. An incision was then made from below the umbilicus to within an inch of the symphysis pubis, the peritoneal cavity opened, and bleeding from the abdominal walls arrested. The bladder was found to be semi-distended, and pushed up above the pubes to the right; the incision was therefore enlarged upwards for about an inch by the side of the umbilicus. An incision of nearly the same length was then made through the uterine wall, which was about one-third of an inch in thickness, when the back of the fœtus was exposed. There was scarcely any bleeding from the incision through the uterine wall. The fœtus was quickly extracted, and the placenta, which was partly detached, was taken out through the abdominal wound with a considerable quantity of partially clotted blood; part of the membranes and cord which remained were drawn out per vaginam. The uterus remained flabby and uncontracted even on pressure. Four interrupted sutures of catgut soaked in chromic acid were put into the uterine wound. The peritoneal cavity w sponged out, and the abdominal wound secured with silv sutures (three deep and three superficial), and supported with straps of carbolised adhesive plaster. The wound was dressed with carbolised lint and tenax, and a binder tightly fastened round. The patient was pulseless after the operation. Hot-water bottles were put to the feet, and her mouth moistened with brandy and water. The operation was completed about 2 P.M. By 4 P.M. she had recovered consciousness, and the pulse, though weak, was distinctly felt, about 120 per minute. In the evening she was feeling better; pulse slightly improved. She complained of thirst and some pain in the abdomen, but said that the previous pains in the back had quite disappeared; the sordes about the teeth had gone, and she took some beef-tea. A draught, composed of twenty-five minims of tincture of opium and a drachm of liquid extract of ergot in an ounce of water, was given, after which she had an hour or two of sleep. Her condition remained about the same until 4 A.M., from which time she began to wander in her mind. When called to see her at 7 A.M., her pulse could not be felt, and she scarcely answered questions put to her. Fifteen minims of ether were given hypodermically, but she did not rally, and died soon after 9 A.M., about nineteen hours after the operation. No post-mortem examination was made.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE BEARING ON THE TREATMENT OF ANEURYSM BY THE INTRODUCTION OF STEEL WIRE OR OTHER MATERIAL INTO THE SAC; REMARKS.

(Under the care of Mr. HOWARD MARSH.)

IT will be remembered that on Feb. 23rd, Dr. Cayley brought before the Medico-Chirurgical Society a case under his care in which Mr. Hulke had introduced forty feet of steel wire into the sac of an aortic aneurysm, with the result that the portion of the tumour acted upon had become completely solidified. Three important points were established by this case, and the discussion to which it gave rise (1) That the introduction of foreign substances into aneurys is usually easy; (2) that, so far as present experience goes, this proceeding appears to involve very little danger when it is carefully carried out; (3) that only nine cases in which this operation has been performed have yet been published,

that our experience of it is far too limited to warrant any conclusion as to its real value. The following instance could be recorded, not only because, while the cases are so few, every additional example is of use, but also because a difficulty was encountered that is very likely to occur, but which has not hitherto been met with.

R. M——, aged fifty-six, formerly a private in the army, never syphilitic, and always temperate, was admitted on Dec. 14th last, having sixteen days before noticed a swelling immediately above the clavicle in the course of the left common carotid, about the size of a bantam's egg, and presenting all the features of an aneurysm. The swelling was well defined above, but its lower border extended beneath the clavicle. On careful examination Dr. Andrew could detect no evidence of intra-thoracic tumour, and the case had the appearance of a sacculated aneurysm limited to the carotid just where it emerges from the chest. Pulsation could, it was thought, be felt in the carotid higher in the neck, but it was very faint; pulsation in the left superficial temporal was very indistinct. The patient said that since the swelling commenced he had suffered much pain in the neighbourhood of his heart, and on the day after admission he had some difficulty of breathing, and pain and numbness extending down his left arm. He appeared in good general health. In consultation with Mr. Savory and other members of the staff, it was agreed that the case was a suitable one for distal ligature. The diminished pulsation in the artery beyond the sac was seen to be an important feature in regard to this proceeding. Mr. Marsh, however, thought it might be explained by the supposition that the trunk of the carotid was overlapped and pressed upon by the tumour, for if the patient's history was correct, that the swelling had existed only sixteen days, it was very unlikely that the artery was already obliterated.

On Dec. 19th Mr. Marsh operated. He exposed the carotid on a level with the cricoid cartilage. Its pulsation was very doubtful, and the vessel felt hard and resistant. Having placed two ligatures (kangaroo tendon) round its trunk nearly three-quarters of an inch apart, he divided the artery between them. This being done, it was found that the lumen of the vessel was entirely filled with a firm tawny clot, adherent to the arterial wall and evidently of some age. From this condition of things it seemed clear that the arterial disease was of much longer duration than the patient was aware of. The healing of the wound progressed favourably; but at 9 P.M. on the 21st he was suddenly attacked with difficulty of breathing, and became very restless. As this condition continued, a fifth of a grain of morphia was injected subcutaneously at 1.30 A.M. He went off to sleep in a few minutes, but his breathing soon became noisy and irregular, and he was partially comatose. Later, his breathing grew still worse, his face was dusky, and he seemed in a dying condition. On being propped up with pillows, however, he improved, the noisy breathing ceased, and he was able to swallow. On the 22nd there was considerable swelling and induration about the wound and in the submaxillary region, with difficulty of deglutition. This attack was associated with marked enlargement of the sac, and the urgent symptoms were no doubt caused by sudden increase of pressure on the structures at the root of the neck. He was now placed on restricted diet, according to Tufnell's method, and kept as far as possible at complete rest. On Jan. 5th it was found that some pus had collected at the bottom of the wound beneath the sterno-mastoid muscle; a counter-opening was therefore made at the posterior edge of the muscle, and drainage secured by a strip of gutta percha tissue. The wound gave no further trouble, and for the next month there was little increase in the size of the tumour, pulsation was less distinct, and the swelling was firmer: so that Mr. Marsh was satisfied with the progress of the case, and thought that deposition of fibrin was going on in the sac. But after this, between February 10th and March 5th, the swelling obviously increased, and became considerably more prominent. It was now determined to adopt the method of introducing some foreign substance into the sac, and on March 10th, having selected a part of the swelling a little removed from its greatest prominence, and where the skin remained unaltered, but where pulsation was yet very distinct and apparently close to the surface, he passed a very fine trocar and cannula about an inch and a half into the aneurysm, and then withdrew the trocar. No flow of blood, however, followed, the cannula remaining as dry as if it had been inserted into a fatty tumour. A fine probe was then passed through the cannula for a distance of fully three inches. It entered readily, but still no blood escaped, nor was the end of the probe at all blood-stained as if it had been in contact with fluid blood. He then endeavoured to pass in some horsehair, but was unable to accomplish this, for as soon as it had traversed the length of the cannula its passage was arrested. On introducing the probe again, its end could be felt moving freely as if in a cavity, and although no blood escaped there was no doubt that the cannula was in the sac, for the pulsation was so distinct that the thickness of the soft parts over the aneurysm could certainly not be more than, at the most, a third of an inch. The supposition was that a portion of the clot had been frayed out, carried before, and was obstructing the end of the cannula, and was also carried in front of the end of the probe, so that the blood stream had not been fairly reached. As the patient was not under an anæsthetic, it was thought best not to proceed further—nor, indeed, was it considered safe to do so; the cannula was therefore withdrawn.

No bad result followed the operation, and Mr. Marsh intended in a few days to introduce the cannula at some other point. The patient, however, was unwilling that this should be done until he had been home, in order to arrange some family business about which he was anxious. He was persuaded to remain quiet for a time. On April 1st, however, he insisted on going out, but said he would return as soon as his affairs were settled. He did so on April 15th, when it was found that, though the swelling had not materially increased, there was an abscess over the front of the sac of the size of a walnut, and covered only by a very thin layer of desquamating cuticle. On the 16th Mr. Marsh divided this, and about a drachm of pus escaped. This relieved the pain he had been enduring; but on the following day the floor of the abscess gave way, and a mass of firm, interlaced fibrinous clot, somewhat dome-shaped, and three inches long and an inch and a half wide, slipped bodily out of the aneurysm, and was followed by a gush of several ounces of blood. The opening was immediately plugged with lint soaked in perchloride of iron. From this time bursts of hæmorrhage occurred from time to time, and were arrested by the introduction of lint and perchloride. Mr. Burd, the house-surgeon, on several occasions passed two fingers into the interior of the sac while introducing the plugs, and bleeding was only arrested by firmly packing the opening, which was at length fully two inches across. It seemed remarkable that the patient could continue to exist in such a condition, yet his death took place only on the night of the 22nd—that is, fully five days after the wall of the aneurysm had given way.

At the post-mortem examination a large aneurysm of the transverse portion of the arch of the aorta, involving the lower part of the carotid, was found. The aorta was extensively atheromatous. The swelling had pressed upon and displaced the trachea.

Remarks by Mr. MARSH.—Several points offer themselves for discussion on this case. 1. As to the seat of the aneurysm. Bearing in mind the overwhelming frequency of aneurysm of the arch of the aorta as compared with aneurysm of the root of the carotid[1], and remembering how often aneurysm of the arch has been mistaken for aneurysm of the vessels which it gives off, both myself and others suspected that, after all, this was an aortic aneurysm. There was nothing, however, to confirm this inference from statistics, unless it were the pain in the region of the heart of which the patient had complained. The pulse in the radial artery, though rather feeble, was not perceptibly weaker than it was in the radial of the opposite side. Auscultation and percussion gave no evidence of thoracic aneurysm, and there was no absorption either of the clavicle or the sternum. On the other hand, the diminished pulsation in the carotid and the site of the swelling were consistent with the view that the aneurysm was a carotid one. The case must be added to many already published which show the great *primâ-facie* probability that an aneurysm at the root of the neck will prove to be connected with the aorta, rather than with any of the vessels which are derived from it. 2. The distal ligature of the carotid was, under the circumstances, useless, as the vessel was already occluded. But it is important to notice that the closure of the artery beyond the

1 Mr. Holmes remarks: "I think I am not mistaken in saying that no preparation exists showing aneurysm limited to the root of the carotid artery on either side, though aneurysms have been found tolerably low down in the vessel."—System of Surgery, Holmes and Hulke, vol. iii., p. 117.

sac by the formation of a firm coagulum—an event precisely similar in its effect to ligature on Brasdor's principle—failed to cure the carotid part of the aneurysm. The case therefore ranges itself with those in which distal obstruction has no beneficial effect on the tumour. 3. I believe the entrance of the horsehair was prevented by the fact that the cannula had been introduced into a part of the aneurysm at which a considerable thickness of coagulum had been deposited. This coagulum, as we found when it was subsequently expelled from the sac, was not of the laminated kind, but resembled rather the loose, though tough, fibrillated clot that is often found interlaced among the columnæ carneæ in the left ventricle. This loose clot was no doubt carried forward on the points of both the cannula and the probe, so that neither of these instruments ever fairly entered the blood stream. 4. Very little experience has at present been gained as to which is the best material for introduction into the sac. In this case I selected horsehair, because, while this substance produced as speedy coagulation in a case under Mr. Bryant as steel wire did in Mr. Hulke's, I thought it would probably do less harm subsequently than the wire would. One could not help fearing that, though wire might become encapsuled, there was a greater probability that it might, later on, act as an irritating foreign body. 5. It was surprising to see to what an extent and for how long a time, plugging of the opening of the sac served to arrest hæmorrhage. As the post-mortem examination showed, here was an orifice in an aneurysm of the aorta and root of the carotid large enough, as Mr. Burd found, to admit the entrance of two fingers into the cavity of the sac. Yet the patient survived for five days, and died at last, not of hæmorrhage, but of dyspnœa and exhaustion.

HOLBORN UNION INFIRMARY.

A CASE OF EXCISION OF THE ELBOW-JOINT, WITH TROUBLESOME HÆMORRHAGE FROM THE BONES; REMARKS.

(Under the care of Mr. OSCAR B. SHELSWELL.)

A GIRL, aged nine, was admitted suffering from disease of the right elbow-joint, caused by injury some months previously. She was of delicate health and had a strong family history of phthisis. Prolonged rest, with arm in splint, effected no improvement. Abscesses were frequently forming about the joint, much discharge and pain existed, which were greatly undermining her health, and the bones were affected to a considerable extent. Excision was deemed advisable.

On May 14th, 1884, whilst she was under the influence of ether, an incision was made longitudinally over the olecranon and made to extend a little upwards and downwards. The condyles were cleaned, and the humerus then thrust out of the wound and sawn off well above the condyles; the head and neck of the radius (leaving bicipital tubercle) and upper part of ulnar, including the coronoid process, were removed. The bones at the line of section appeared healthy. One artery was tied with catgut, drainage-tube inserted, skin sutured with silver wire, wound dressed with carbolic oil, and Mr. Bryant's screw splint applied. A little oozing came on two hours after the operation, which subsided with the usual remedies, but recurred later on. As the former treatment failed to arrest it this time, and as the hæmorrhage was rather sharp, the wound was reopened at 11 P.M. under ether. No artery was seen spurting, but there was very considerable oozing from the cut ends of the bones. The actual cautery was applied, and after some difficulty the hæmorrhage ceased. The wound was plugged with iron and the arm firmly bandaged. The splint was kept on only a few days, as she seemed more comfortable without it. A small piece or two of dead bone, due to the cautery, came away, and the wound healed by granulation. Excellent movement resulted, pronation and supination being satisfactory and flexion and extension perfect, the arm being very useful, quite free from pain, and the girl vastly improved in health—in fact, quite well. She then left the infirmary and went to school, where she received a blow on the arm, which caused a little inflammation; this, however, subsided with rest, and the arm is now in a satisfactory condition.

Remarks by Mr. SHELSWELL.—I think this case is interesting as showing the necessity of removing an ample amount of bone in cases of excision of the elbow. It seems probable that the troublesome hæmorrhage from the bones in this instance was in consequence of the latter not being perfectly healthy at the time of division, notwithstanding the fact that so much was removed, the advice of Mr. Bryant to be free in the section of the bones being w[illegible] borne in mind at the time of the operation. If such be the explanation it is probable that the good result was in consequence of the cautery destroying a little more of the bones, and thus satisfactorily preventing the necessity of a second operation.

NORTHAMPTON GENERAL INFIRMARY.

COMPOUND DEPRESSED FRACTURE OF THE SKULL INFLICTED BY A PISTOL; WOUND OF THE FACE; TREPHINING; RECOVERY.

(Under the care of Mr. R. A. MILLIGAN.)

FOR the history of this case we are indebted to Dr. J. Oswald Lane, late house-surgeon.

T. B——, aged forty-five, was admitted on March 4th, 1886, with the following history:—The evening before, after shooting his sweetheart and father, he shot himself in the face with a pistol loaded with No. 5 shot. He then ran into a neighbouring wood, and lay there hiding from his pursuers till 8 A.M. the next morning, when, [illegible] capture, he shot himself in the skull.

On admission, about 3·30 P.M., he was found to [illegible] ing from two gunshot wounds. One on the right cheek, just below the zygoma and in front of the ear, was of a punctured character, with lacerated edges, a probe passing upwards and forwards subcutaneously an inch and a half. Another wound was found in the right parietal region, two inches and a half from the sagittal and two inches from the coronal sutures, also punctured and with lacerated edges, circular in shape, and half an inch in diameter. On probing, it was found to lead down to a depressed fracture of the parietal bone. Numerous shots could be felt under the scalp, especially about the forehead. The patient was conscious and answered questions rationally, stating that he had inflicted the wounds, and that he had never lost consciousness. At 5 P.M. he was put under ether, and, antiseptic precautions being taken, Mr. Milligan enlarged the wound over the fracture, removed the pericranium, trephined away a piece of bone adjacent to the fracture, and was then able to remove a depressed portion of bone of small size, and also four pieces of the inner table, which had been splintered and driven on to the dura mater, which, however, was not torn through; several shots were found underneath the depressed bone. The edges of the wound were brought together with wire sutures, and a drainage-tube introduced. Carbolised gauze dressings were used.

March 5th.—The patient passed a good night, having slept well. This morning he complained of slight headache. The wound was dressed, and looked healthy; slight hæmorrhage had occurred, but was soaked up by the dressings. Ordered three pints of milk, and ice-bag to the head. Pulse 84; respiration 28; temperature 99°.

8th.—Has gone on well; no head symptoms; wound is beginning to show granulations; has been dressed daily; temperature has not been higher than 99·6°.

9th.—Complains of rather more pain in the head, and there was found to be some œdema of the scalp and rather more discharge from the wound in the cheek. Several small incisions were made in the scalp.

10th.—The patient is rather more restless. There is some bagging of pus near the trephine wound; so two counter-openings were made and drainage-tubes inserted.

12th.—General condition much improved; purulent discharge much diminished.

15th.—From this date the patient progressed most favourably without any further complications, so that at the end of the month he was allowed to sit up in the ward. He was tried the next month on the capital charge, and is now an inmate of Broadmoor.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—The annual meeting of this Society was held on the 2nd inst., Mr. Joseph White, President, in the chair. The following gentlemen were elected to fill the various offices for the ensuing session:—President: Mr. Hatherly. Vice-Presidents: Mr. Joseph White and Mr. Haydon White. Treasurer: Mr. Stanger. Hon. Librarian: Mr. Burnie. Hon. Secretaries: Dr. B. A. Whitelegge and Mr. T. D. Pryce.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Chronic Abscess of Female Urethra.—The Uterine Bruit.

A MEETING of the Society was held on July 7th, Dr. Potter, President, in the chair.

The following specimens were shown:—Dr. Daly: Growth removed from Uterus after delivery. Mr. Doran: Malformations of the Fallopian Tubes. Dr. Galabin: Growth removed from Cervix Uteri of a girl only seventeen years old. Dr. W. S. A. Griffith: Portions of Ovaries resembling Cystic Chorion. Mr. Knowsley Thornton gave details of the fatal termination of the case from which the specimens he showed at the previous meeting were removed.

Dr. HERMAN read a paper on a case of Chronic Abscess of the Female Urethra. The patient, aged forty-seven, had for four years suffered from dysuria, about two years from dyspareunia, and irritability of bladder, these symptoms gradually increasing in severity during this time. There was a tender swelling between the urethra and vagina. This burst into the urethra, pus being discharged. Examination with the finger through the dilated urethra eight days afterwards showed that the cavity was then about the size of half a walnut, with a soft, ragged, friable wall. Its interior was cauterised with nitrate of silver, and it soon contracted and disappeared. Four months afterwards the patient continued quite well. The author thought that there were two possible explanations of the origin of the abscess:—1. That it was the result of chronic congestion of the urethra, such as that described by Sir C. M. Clarke. 2. That it was a suppurating cyst. Abscess from either of these causes was rare. He quoted three cases that he had been able to find recorded. He gave reasons for thinking that the abscess in his case was probably not a suppurated cyst, and that the case was therefore to be classed with those of congestion of the urethra described by Sir C. Clarke and Dr. West.—Dr. DALY said that in a case of congestion of the female urethra which had resisted all treatment, the patient being for months confined to bed and suffering intense pain, he applied iodoform every day along the entire course of the urethra, and obtained a rapid cure. The application was made by filling the groove of a director with iodoform, and when the director was well in the urethra reversing the direction of the groove. He had to thank Dr. Herman for the suggestion.—Dr. MATTHEWS DUNCAN had seen many abscesses in the recto-vaginal septum, but he remembered none in the urethro-vaginal septum. Chronic urethritis he had often seen, and also some cases of urethrocele.—Dr. GERVIS, though surprised at the statement in Dr. Herman's paper as to the rarity of the condition described, could certainly only at the moment recall one case. In this the symptoms had been painful micturition, without evidence of cystitis, and pain, swelling, and tenderness referred to the vagina. On examination an abscess was found in the anterior vaginal wall in association with the urethra, and the same evening, probably as a result of the examination, which included the passage of a sound into the bladder, the abscess burst into the urethra, and the patient made a good recovery.—Mr. KNOWSLEY THORNTON had seen a few cases of the kind. He would raise the question as to whether the condition described by Sir C. Clarke was the same as that for which Dr. Emmet, of New York, had invented a special operation. If so, the condition must be much more common in America than in this country.—Dr. WYLIE (New York) said that the condition for which Emmet's operation was chiefly used was prolapse of the mucous membrane of the urethra in elderly females.—Mr. DORAN referred to an interesting case of a diverticulum in the female urethra, described by Sautesson of Stockholm, and published in the *London Medical Record*, March, 1885. The symptoms were very puzzling until the parts had been carefully explored.—Drs. GALABIN and M. HANDFIELD JONES also made remarks, and Dr. HERMAN replied.

Dr. CHAMPNEYS read a paper entitled "Observations on the Uterine Bruit." The author records a series of observations on this point, some of which have been already reported in this country, some abroad only, and some are recorded, it is believed, for the first time. The first series includes forty-six nearly continuous observations made at the General Lying-in Hospital regarding (1) the position of the maximum intensity before labour; (2) after the expulsion of the placenta; (3) the presence of pulsating arteries felt by the vagina, and the effect produced on the bruit by their compression. The bruit was heard on the left side in thirty-three cases; on the right side in one case. It was heard after the expulsion of the placenta in five cases. In all cases when heard after the expulsion of the placenta its point of greatest intensity had sunk down after delivery. In five cases a pulsating artery was felt in the vagina; pressure on it affected the bruit in one case only. The preponderance of left-sided over right-sided bruits confirms the view that the bruit is produced in the arteries as they reach the uterus or soon after, the left corner of the uterus being anterior to the right (dextral torsion). One observation concerns a case of placenta prævia, in which the bruit and the placenta were on the left side. The author analyses Rapin's and Rotter's papers, the latter of which concerns the relation between a uterine bruit heard and a thrill felt. The author records two cases in illustration of the same point, and one case in which the same observation was made in the case of a fibroid tumour of the uterus, also one in which post-mortem examination seemed to show that a uterine bruit was situated in a large sinus running over the surface of a fibroid tumour.—Dr. GERVIS asked why Dr. Champneys adopted the term "palpable bruit" to express the perception of a localised pulsation, and also whether in the course of his observations he had found corroborative evidence of Dr. Hicks's suggestions as to the effect of the uterine contractions on the characters of the souffle.—Dr. HERMAN thought that the variations in loudness of the murmur to which Dr. Gervis had referred were of much importance in its identification. There was no kind of abdominal enlargement in which a murmur having rhythmical variations in loudness was heard excepting that produced by uterine tumours. The presence of such a murmur showed that the tumour was uterine, but did not give any further information as to its nature. The murmur might be as a rule louder and the variations more marked in pregnancy than in fibroids, but he had heard murmurs over some fibroids louder than those in some cases of pregnancy. The murmur was not to be relied upon for the diagnosis between fibroid and pregnancy.—Dr. JOHN PHILLIPS asked if Dr. Champneys had any experience in vaginal stethoscopy, and if so whether it was corroborative of the hypogastric signs. He was aware that there was naturally a certain feeling of aversion to this method of diagnosis, but thought that if any facts of scientific value could be thus obtained it might be permissible or even advisable.—Dr. A. ROUTH asked how long the uterine souffle persisted (1) after labour, and (2) after the death of the fœtus in utero. He had seen a case at Charing-cross Hospital where labour had to be induced for incontrollable vomiting, in which vaginal stethoscopy proved the souffle to exist two or three weeks after the presumed death of the fœtus, which was mummified, the souffle being inaudible over the abdomen. He had frequently heard the souffle per vaginam over the cervix uteri when it was inaudible over the abdomen; and, so far as his experience went, he had found that whenever the souffle of a pregnant uterus was audible over an abdominal area it was always audible over the cervix uteri per vaginam. In one case of the souffle being heard in the abdomen over the site of a uterine fibroid, it was not audible over the cervix uteri. If this distinction of the area of diffusion of the souffle of pregnancy and of that of a uterine tumour be trustworthy, it would serve as a material aid in differential diagnosis.—Dr. W. S. A. GRIFFITH thought that the dextro-torsion of the uterus, which only occurs to a very limited extent, was by itself insufficient to explain the frequent absence of the uterine souffle on the right side. Some other explanation was wanted which would apply equally to the cases in which it was absent on both sides. The great cause of the bruit was almost certainly the passage of blood suddenly from a small into a larger channel at the junction of the uterine arteries and sinuses.—Dr. CHAMPNEYS, in reply, said that the subject was so large that he had not attempted a complete study of it; in this sense his observations were confessedly imperfect. By "palpable uterine bruit" he meant a bruit which was also palpable as a thrill. He was inclined to agree with Dr. Herman that marked rising in pitch was characteristic of the souffle in pregnant uterus rather than in fibroid. He had not used the vaginal stethoscope, as the gain was very questionable and the objections obvious. He had never

observed dicrotism in the souffle. The souffle was often musical, the various notes forming a sort of chord, and this pointed to their being produced by many vibrating bodies. He could not answer the question as to the exact length of time the souffle was audible after delivery without referring to the hospital notes. The entrance of blood from a small into a large cavity was probably the chief cause of the souffle; but there were many other sufficient causes, such as the sudden curves in the arteries, the quality of the blood, &c. It was difficult to eliminate these.

ACADEMY OF MEDICINE IN IRELAND.

Nature and Surgical Treatment of Scrofulous Cervical Glands.

A MEETING of the Surgical Section was held on April 16th.

Mr. KENDAL FRANKS read a paper on the Nature and Surgical Treatment of Scrofulous Cervical Glands. The paper dealt, in the first instance, with the connexion between scrofulosis and tuberculosis. The history of the discussion regarding the identity or non-identity of the two affections was traced, and Mr. Franks showed that the conclusion arrived at up to the spring of 1882 was that the two diseases could not be separated—that they were both caused by the same virus, but that the nature of this virus had not been recognised. The discovery of the tubercle bacillus in that year had, however, settled the question, and the presence of the bacillus in all so-called "scrofulous" affections proved their tubercular nature. Thus scrofulous disease of joints, caries, cold abscesses, and "strumous" glands must henceforth be all classed under the head of tubercular diseases. Tuberculosis of the cervical glands was shown to be the result of the entrance of the tubercle bacillus at some contiguous abraded part, and most cases could be traced back to some local affection, such as eczema of the head, ulcers in the mouth, sore-throat, and so forth, all of which afforded a nidus for the bacillus. The constitutional peculiarity, the "vulnerability of tissue," was a most important factor in determining a proper soil for the development of the organism, and much depended on the dose of the poison received as to the future progress of the case. Three courses were open to the gland to pursue:—First, death of the bacillus and consequent resolution; this was not usual. Secondly, suppuration and expulsion of the tuberculous virus; this might occur in one gland after another, and was of common occurrence. Thirdly, the extension of the disease along the course of the lymphatic glands, and if this were not arrested, subsequent generalisation of the disease. Mr. Franks urged that surgical measures should be guided by our present knowledge of the dangerous nature of the disease; and that constitutional measures, which should be used in all cases, should not be trusted to exclusively, once the diagnosis as to the tubercular nature of the disease was established. He referred to three surgical measures as being the best, each of which was applicable to its own class of cases. 1. *Scoopidy* should be confined to cases in which a sinus already existed, or in which a superficial abscess was connected with a caseous gland beneath the cervical fascia (Teale). 2. *Cautery puncture*, recommended by Treves, was most applicable to softened caseous glands which had formed extensive adhesions. 3. *Excision*, which had the widest applicability, was chiefly suitable in cases where the glands were still hard and movable. It was applicable to extensive disease as well as to more limited cases; but he urged that it should be employed early, when practicable, before softening or adhesions were formed. It was then possible to eradicate the disease through a small opening, and thus save the patient from an extensive operation subsequently, or, if that were not resorted to, to a prolonged and exhausting process of suppuration.—Mr. THOMSON was not quite sure that surgeons could boast, what seemed to follow from Mr. Franks' assertion, that, in the treatment of scrofulous cervical glands, they had invaded territory which had heretofore been largely in the hands of the physicians. It was common experience that the physician's treatment often averted what appeared to be a threatening disaster; but there was a large proportion of cases which went to the bad, and, as to their surgical treatment, had been until lately in opprobrium. The present impetus to surgical treatment was due, perhaps, to Teale and Allbutt more than to anyone else. So far as internal treatment was concerned, he had found an extremely good remedy in chloride of calcium, given in from ten to fifteen grain doses, three times a day, continued for several months.—Dr. HENRY KENNEDY mentioned, as a surgical point worth remembering, that, having been repeatedly asked to deal with a single suppurating gland, he used simply a thread seton, passing a needle through the length of the suppuration.—Mr. CORLEY was impressed with the expediency of early removal of the glands, but not too early, because there was the chance of removing glands which probably in the ordinary course would disappear of themselves.—Dr. BENNETT regarded the incision of the glands in the neck as disastrous, it being impossible to say when the limit of operations would be reached, while there generally followed disease of a more disseminated type. He suggested that when a single gland or two happened to be engaged, and there was a difficulty of diagnosis between a scrotulous gland and a gland enlarged by irritation, the passing the point of a subcutaneous syringe into the substance of the gland with an injection of tincture of iodine would be beneficial.

On the Quantitative Estimation of Sugar in the Urine by the Polariscope.—Lichen Planus.

A meeting of the Medical Section was held on April 30th.

Dr. CRUISE read a communication on the Estimation of Sugar in the Urine by the Polariscope, and demonstrated the operation with the instrument known as the Yvon-Dubosco Diabétomètre. He dwelt upon the great advantages of this method over volumetric analysis, inasmuch as it is very accurate, very easily used, and occupies only about ten minutes; while chemical determination is surrounded by errors, both possible and serious, requires special skill, and can scarcely be accomplished in less than an hour.—Dr. TICHBORNE said he was indebted to Dr. Cruise for his introduction to this instrument, and was in a position to bear testimony to the utility of this very excellent polariscope, which would be effectual in estimating the quantity of sugar in any substance. The paper issued by the makers of the polariscope stated that either charcoal or acetate of lead might be used for decolourising the urine. He thought that charcoal was not desirable because it slightly reduced the percentage of sugar. He had found that where charcoal was used the amount shown was '85, while in the case of acetate of lead it was '94; so that the use of charcoal involved a sacrifice of accuracy, and care should be taken not to use more acetate of lead than sufficed to decolourise the urine. Unless the fluid were perfectly bright, it could not be used; but if an over-quantity of the acetate were employed, the fluid would be rendered sensitive to the carbonic acid of the atmosphere, and would become muddy almost as quickly as it was filtered. The speaker was in the habit of adding a few drops of a solution of basic acetate of lead, the quantity being determined by the intensity of the colour of the urine; water was then added in sufficient quantity to double the volume of the urine. By this method an excess of acetate of lead was avoided, and it was only necessary to multiply the results obtained by twenty to gain the percentage. In some cases the volumetric analysis could be more relied on than this polariscopic method; but, generally speaking, the latter proved the more trustworthy in two out of three cases. In using the polariscope it was necessary to guard against fluctuations of temperature, and also too high a temperature. Each degree of Fahrenheit made as much difference as 2 in the rate of rotation exhibited with inverted sugar, and also a considerable difference in right-handed rotation. He had found that 60° F. was the best temperature in which to use the method.—Dr. WALTER SMITH said this instrument was sufficiently accurate for clinical purposes. If great accuracy were required, the palm must be yielded to chemical methods. This optical method was not reliable for percentages of sugar smaller than ½ per cent. It was not a sensitive test of sugar, for it went on the assumptions that urine contained no active substance except glucose, and that the optical behaviour of glucose was the same as that of distilled water. But the first of these assumptions was not true. Of late years it had been conclusively shown that in diabetes the urine contained not only glucose, which was dextrogyrate when seen optically, but also a peculiar acid, which was lævogyrate. In such a case the amount of sugar would be represented by the difference in rate between the two gyrations. Again, it had been made out that a large class of substances, several of which were now used in medicine, passed out in the urine in

a chemical form, which excited a left-handed rotation in polarised light. This was true of a large group of bodies, including aromatic compounds, alcoholic derivatives, chloral, &c. Therefore the polariscope could not be accepted as an exciting determinant of the amount of sugar in diabetic urine.—Dr. NIXON said he agreed with Dr. Smith that strict scientific accuracy could not be obtained by the polariscope exhibited. He had for some years used the instrument of Soliel-Ventzke, of which the present one was a modification. The chief difficulties in connexion with its use were—first, the trouble it involved in decolourising the urine; secondly, that some nice manipulation was required in order to prevent bubbles of air from getting into the glass tube; and thirdly, that after each application the indiarubber washer usually got firmly attached to the glass slide, and necessitated some trouble in removing it. These difficulties, however, were got over by a little practice in the use of the instrument.

Dr. FINNY remarked upon the rarity of Lichen Planus in this country, and quoted Dr. Taylor, of New York, and Erasmus Wilson in support of the same rarity in America and England. Dr. Finny had never before met with any similar case, although for over twelve years he has had, weekly, an opportunity of studying diseases of the skin at the hospitals. The case was a very extreme example of lichen planus, as with the exception of the head and face, the papules invaded every part of the body. The patient, Mrs. H——, aged fifty-three, had never before had any cutaneous affection. She was supposed to be rheumatic and dyspeptic. For some months her nervous system seemed to have been depressed, as she was easily tired and became irritable. On two occasions her bowels moved suddenly in the street, although she had had a natural evacuation in the morning. Her life was an easy one, and her circumstances comfortable. She consulted Dr. Finny at the end of August, 1885, for a very itchy affection of the skin, of six weeks' duration, the irritation of which had quite deprived her of sleep and caused loss of appetite. The disease began in small patches below the knees, and gradually spread, until in the first fortnight of September there was no part devoid of papules except the head and face. The eruption was, however, both as to the size of the papules and extent of the patches, greatest over the back, loins, abdomen, and vastus internus of the thigh. The papules in the palms and soles were few and scattered. The colour was very striking, being of a dull or purplish red, and resembled a papular syphilide. Each papule (2 to 6 lines) had characteristics peculiar to the disease. It was solid, free from all serous or purulent discharge, abrubtly raised from the adjoining skin, round or polygonal in outline, with sharply defined edges. Its surface was smooth, waxy, or glazy, to which, in some but by no means all instances, was attached a slight filmy desquamation. Many of the papules were slightly depressed or quasi-umbilicated. The papules formed extensive plaques, and, by their contiguity rather than their confluence, they produced a peculiar tesselated or mapped-out appearance of the skin. In such places the pigmentation of the skin was between the papules, which stood out whitish-grey on a brown-red ground. The treatment consisted in narcotics and hypnotics to procure sleep, and in the internal administration of arsenic, the dose of Fowler's solution being pressed up to 13 minims three times a day, until its physiological effects were produced; it was then intermitted, and, on resumption, was continued for a month after improvement had set in. The local remedies which gave most relief to the pruritus were warm alkaline baths and a lotion of carbolic acid and liq. carbonis deterg. Profuse diaphoresis from pilocarpine was also of use in the early stage. A fortnight after treatment by arsenic improvement commenced, and at the end of October, six weeks from the inception of its use, not a papule remained, though the skin for many weeks subsequently was deeply stained and mottled.

PLYMOUTH AND DEVONPORT MEDICAL SOCIETIES.

A MEETING of these conjoint Societies was held on March 24th, Mr. Geo. Jackson, President of the Plymouth Medical Society, in the chair.

The PRESIDENT showed a case of Ichthyosis of the Lower Lip, with Leucomatous Patches inside the cheeks, occurring in a man who had worked inside the double bottoms of ships, with no apparent ill effects at the time. He also showed Kidneys removed from a man who had complained of no symptoms of kidney disease during life. One kidney was much hypertrophied, the other atrophied, and the subject of cystic degeneration.

Dr. WILLIAM H. PEARSE read a paper on Cholera. He argued that the facts of miasmatic contagion and of the autogenesis of cholera must both be admitted, and were embraced in a greater theory of evolution. He applied Darwin's hypothesis of pangenesis to the autogenesis of cholera. He maintained that "changed" environment had been followed by cholera, and held that vito-chemical poisons evolved, after periodic intervals, from varied "shocks" or *extremes* of environment. He applied the doctrine of "continuity" to cholera, and suggested the method of coördination to those not visibly affected.

Reviews and Notices of Books.

Dictionary of Practical Surgery. By various British Hospital Surgeons. Edited by CHRISTOPHER HEATH, F.R.C.S. London: Smith, Elder, and Co. 1886.

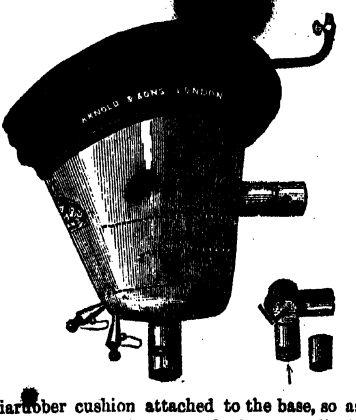
THE success which the Dictionary of Medicine has achieved no doubt prompted the idea and led to the production of a kindred work on Surgery. This Mr. Christopher Heath has satisfactorily accomplished, with the aid of one hundred and sixteen different contributors, the majority of whom are well-known as surgeons or physicians to the metropolitan or provincial schools, many amongst them having attained the highest distinction as *littérateurs* in medicine and surgery. One of the first duties of the editor of a work of the kind before us is the selection of contributing authors, and the assignment to each, so far as may be possible, of subjects on which he is known to be especially informed, and therefore best qualified to expatiate. It is to the very judicious way in which the labour has been distributed by Mr. Heath and his coadjutors that the Dictionary of Surgery will largely owe the full measure of success which we have no doubt will be accorded to it, since a large number of its contributors are eminent authorities upon the subjects allotted them, thus adding greatly to the value of the work as a book of reference. The aim of the editor, as stated in his preface, has been to produce a compendium of the practice of British surgery, which may supply a want in the library of the busy practitioner, who necessarily often meets with cases of surgical disease or injury on which he desires to have immediate information as to diagnosis and treatment. With this view a series of articles on the diagnosis of the injuries and diseases of the several regions of the body, and general articles on Deafness, the Eye, Skin Diseases, &c., have been introduced, the subjects being treated of, so far as is practicable, in the following order: (1) Cause; (2) pathology; (3) symptoms and diagnosis; (4) treatment; and (5) prognosis. We take it that the chief advantages claimed for a Dictionary of Surgery over a system or treatise should lie in the conciseness and trustworthiness of the information supplied, and its ready accessibility by virtue of the adoption of the alphabetical arrangement of the subjects treated of; and in the present instance a further advantage may be presupposed, insomuch as the Dictionary in question is the outcome of the experience of many individuals, the editor having "exercised a general supervision," and "endeavoured to prevent the promulgation of crude theories or the inculcation of doubtful practices." With respect to the purely editorial work of compilation, faults we think there are, both of omission and commission; but on the whole it has been well done. Among subjects which are not indexed, and have no special alphabetical headings, are congenital tumours, bronchial cysts and fistulæ, congenital tumours of the sterno-mastoid, actinomycosis, caries of the ribs, and pericostal abscess; whilst we could not light upon any

reference to tropical abscess of the liver, a subject which surely comes within the domain of surgery. Again, the surgical aspects of laryngeal and pharyngeal diphtheria, and tubercular or scrofulous kidney, which in other text-books commonly receive separate treatment, are dealt with somewhat cursorily in articles devoted to other matters. Sometimes what would seem to be useless repetitions occur: for instance, in the first volume is an article on Scald of the Larynx; another may be found in the second volume headed Scald of the Glottis, occupying twice as much space as the former, written by a different author, and traversing much the same ground. A large and even superabundant amount of space has been given to descriptions of various surgical appliances and instruments, well written by Mr. Bilton Pollard, perhaps at the expense of other subjects which deserved fuller notice: for example, the article on Specula monopolises no less than five columns; whilst the general article on the Surgical Diseases of Children is dismissed in four. "Doubtful practice" has, too, sometimes found its way in. As an instance, we may cite the assertion of Mr. Paul Swain, in his article on Masturbation, that "the application of nitrate of silver to the prostatic urethra" is of service in the treatment of that most pernicious habit. We think that very few surgeons would be inclined to adopt this method, which many deem unjustifiable.

The articles are so numerous and so compressed that a detailed or systematic criticism is out of the question; we therefore can but briefly refer to those which by the fact of their importance, special prominence, or for other reasons, merit the reviewer's notice. With respect to their substance, every one is cognisant of the difficulties which beset the compilers of an encyclopædia or dictionary in which a number of writers are concerned; thus it happens that an article on which much of the author's energy has been expended in carefully eliminating unimportant passages and redundancy of words, in order that in length it may fulfil the conditions of space imposed upon him by the editor, is mercilessly cut down or ordered to be rewritten, because, like many a good picture rejected by the hanging committee of the Royal Academy, it did not coincide with a certain superficies to be covered. Yet the reader is bound to hold the unfortunate author responsible for any delinquencies discoverable in the articles endorsed by his signature, whether they be the result of editorial excision or not. In General Surgery, Professor Stokes of Dublin has written a series of valuable essays on amputations generally, and on amputations of special parts. Mr. Jonathan Hutchinson writes characteristicly and almost irreproachably on Syphilis and allied subjects. A short but highly suggestive article is contributed by Sir James Paget on Old Age. Mr. Heath writes the sections on Aortic and Innominate Aneurysm, and the Surgery of the Jaws, his special knowledge and experience in these subjects being already well recognised and appreciated, together with a general article on Abdominal Surgery. Dr. William Murray, of Newcastle, naturally treats of Abdominal Aneurysm. Diseases of the Bladder, Stricture of the Urethra, and dependent subjects have been assigned to Mr. Berkeley Hill; Tumours of the Bladder to Sir Henry Thompson; Rupture of the Bladder to Mr. Rivington; Lithotomy and Lithotrity to Mr. Cadge of Norwich, and Urinary Calculi to Mr. Crosse of the same town: these matters have been practically and thoroughly dealt with by these authors in excellent articles. The sections on Diseases and the Surgery of the Kidney have been entrusted to Mr. Arthur E. Barker. The article headed Nephritis is somewhat meagre, only covering two and a half columns; in it but little attempt is made, either in a clinical or pathological sense, to differentiate between the kidney changes and associated symptoms of the various forms of Bright's disease, and those due to retention and back pressure of the urinary excretion, or the septic decomposition of the latter. In the article on Pyelonephritis we are in some doubt as to what is meant by the phrase "the 'overflow' of bad retention": the same author's account of the operative surgery of the kidney, and also that of the pylorus, is, however, very acceptable. We do not understand why the tests for albumen in the urine are not incorporated in the article on Albuminuria, written by Mr. Mansell Moullin; they are to be found, nevertheless, fully described under that of Morbid Conditions of the Urine; in fact, the whole subject of albuminuria is there again fully gone into. Diseases of the Breast are ably discussed by Mr. Marcus Beck; and of the Testis, by Mr. Pearce Gould, who also writes admirably on Popliteal Aneurysm and other subjects. Mr. Bond subscribes the article on Railway Injuries, considered chiefly in their medico-legal aspect; whilst Mr. Herbert Page contributes an original and well-written section on Injuries of the Back and Spine. In the Surgery of War, Sir William Mac Cormac is in his element in matters relating to Gunshot, Sabre, and Bayonet Wounds; and Mr. Cantlie writes on the Ambulance, the Management of the Sick-room, with other articles on Surgical Anatomy and methods of Ligature of Arteries. The work of Mr. Treves is varied, thorough, and concisely written; he subscribes the sections headed Air in Veins, Intestinal Obstruction, Strangulated Hernia, and a number of others devoted to the Surgery of the Intestine, as well as those on Diseases and Injuries of the Lymphatics. No one more competent could have been selected as the author of the article on Cleft Palate than Mr. Thomas Smith; or on the subjects of the Plastic Surgery of the Bladder and Urethra, and Radical Cure of Hernia, than Mr. John Wood. Many other articles are equally meritorious: among them are those on Fractures, by Mr. Marsh, who, moreover, contributes an excellent section on Hip Disease; on Dislocation and Wounds of Joints, by Mr. Clement Lucas; on Injuries of the Chest and Lung, by Mr. Howse,—to the same writer being apportioned the subjects of Femoral Aneurysm and Gastrostomy; on Empyema, by Mr. Godlee; on the Treatment of Wounds and other collateral subjects, by Mr. Sampson Gamgee; on Congenital Dislocations, by Mr. George Cowell; on Tetanus and Diseases of the Rectum, by Mr. McCarthy; on Erysipelas and allied subjects, by Mr. Pickering Pick; and on Diseases of the Tongue, by Mr. Morrant Baker. There is little to find fault with in the contributions of Dr. William Macewen of Glasgow on Osteotomy, Grafting, and those relating to Head Injuries; but might not the indications and methods of trephining for meningeal to hæmorrhage have been more precisely set forth? Mr. Barwell's views of the pathology of Scrofula are somewhat out of fashion; his notion that "rachitis is probably a scrofulous affection in the large majority of instances" will, we are inclined to think, hardly meet with general acceptance. In marked contrast to this writer's views of the relations of scrofula to tubercle, are those expressed in a carefully written article by Mr. Makins on Surgical Tuberculosis. It may be mentioned here that, whilst Mr. Makins fully considers the subject of tubercular diseases of the joints in their varying aspects, mainly of course from a pathological point of view, Mr. Warrington Haward, in his general article on Diseases of the Joints, which in other respects is excellent, gives no special designation to this class of cases; but, using the term "scrofulous," he apparently includes in that category those affections of the joints which are now classed as tubercular, and makes no reference to the fact that the bacilli of tubercle are demonstrable in the diseased structures connected therewith. Mr. Pepper writes with remarkable perspicacity on a variety of subjects. Mr. Victor Horsley may be said to be ubiquitous; but, although precise and

accurate in his terminology and classification of septic processes and organisms, he is not always practical. It would be invidious not to mention the names of many writers who have done good work often in matters of minor import: such as Mr. Watson Cheyne, Mr. Boyd, Mr. Ballance, Mr. Golding Bird, Mr. Bellamy, Mr. Davies Colley, Mr. Clutton, Mr. Morgan, Mr. Mason (so lately deceased, and who wrote the article on Nævus), Mr. Dent, Mr. Symonds, Mr. Johnson Smith—the general subeditor,—and others. A commendable feature of the Dictionary is the introduction of sections upon Regional Diagnosis and Surgical Anatomy; they are, as a rule, trustworthy and practical guides. In more special subjects, Mr. Robert W. Parker and Mr. Owen have appropriately been assigned the greater number of the articles on the Surgery of Childhood; Dr. Barlow and Dr. Gowers write on Cranio-tabes and Pseudo-hypertrophic Muscular Paralysis respectively; whilst Mr. Henry Baker treats of Tenotomy and Club-foot: in the article on the latter subject, only a few lines are devoted to the pathology of the congenital variety, which the writer believes "to be due to disordered nervous function acting upon the muscles, which draw the foot into its deformed position"; and we think that the comparatively recent investigations of Messrs. Parker and Shattock into the pathogeny of this affection might at least have been referred to by the author. Gynæcological Surgery could hardly have been better cared for than in the hands of Mr. Knowsley Thornton and Mr. Doran. Diseases of the Larynx and Thyroid Gland have been assigned to Dr. Semon; of the Ear to Messrs. Field, Purves, and Cumberbatch; of the Teeth to Mr. Tomes. Dr. Stephen Mackenzie discourses on Chyluria and Filaria Sanguinis Hominis; Mr. Shirley Murphy on Vaccination: so that it will be seen that topics which are but on the threshold of surgery have been admitted to a place.

The value of the Dictionary is much enhanced by the incorporation of a series of essays on Ophthalmology and Dermatology; both subjects are treated with a completeness notably absent in some of the other more special departments. The articles, though often widely separated, really form a connected whole, and, for the most part, attain to a high standard of excellence. Mr. John Tweedy has supervised the articles on Affections of the Eye, and Dr. Robert Liveing those on Diseases of the Skin, than whom Mr. Heath could hardly have found two more capable coadjutors. In matters relating to the eye, a number of ophthalmologists are associated with Mr. Tweedy, whose names are a sufficient index of the character of the work done by them; they include Mr. Lawson, Mr. Power, Mr. Brudenell Carter, Mr. Priestley Smith, Mr. Marcus Gunn, Mr. Berry of Edinburgh, Mr. Charnley, and others. All have brought a large, and often special, experience to bear upon the subjects with which they are connected, and much new and original matter may be found scattered through their several articles; the most obvious fault to be found with the latter is that they bear some evidence of undue compression. Two exhaustive and interesting articles may be referred to here: one by Mr. Herbert Page on Disorders of Vision from Injuries of the Head and Spine; another by Mr. Rivington on Orbital Aneurysm. In matters dermatological Dr. Liveing has written largely and instructively himself, his colleagues being Mr. Malcolm Morris, who in an important contribution identifies himself with the subject of Lupus, Dr. Cavafy, Dr. Radcliffe Crocker, and Mr. Alfred Sangster.



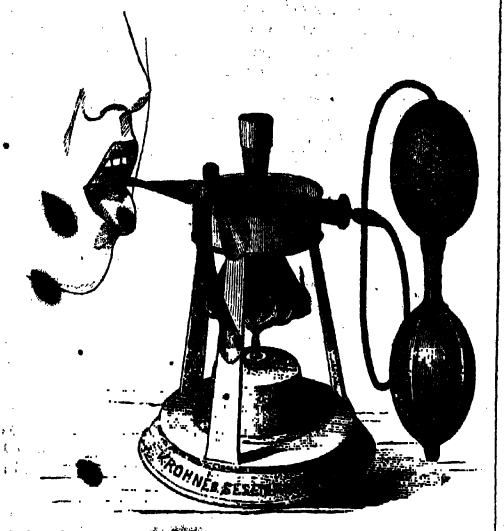
An adjunct of great utility is the insertion of a full index at the end of Vol. II., whereby subjects which have received no separate heading but are discussed in another place, and would thus be difficult to light upon, are at once easily discoverable. The Dictionary takes the form of two conveniently sized and well-bound volumes, the type employed, though small, being clear and legible.

Mr. Heath is to be congratulated on the accomplishment of a work which, on the whole, is one of high merit, and alike creditable to himself and to the majority of those who have been associated with him; and the more so, since the compilation of the Dictionary progressed notwithstanding a severe and prolonged illness—terminating, happily, in complete recovery—which overtook him after he had commenced his editorial duties. We cannot close this brief review without expressing our admiration of the energy and perseverance which, amidst so many difficulties, have brought an arduous and anxious undertaking to a satisfactory and successful conclusion.

New Inventions.

GENERAL ANÆSTHETIC INHALER.

FEELING somewhat dissatisfied with all the anæsthetic inhalers at present in use, Messrs. Arnold and Sons, West Smithfield, E.C., have most ably made for me a "General Anæsthetic Inhaler" according to my instructions, as depicted in the accompanying woodcut. This may be termed a good "all round" inhaler, as it can be used for nitrous oxide gas, chloroform, ether, alcohol, or methylene bichloride, given either separately, mixed, or successively, as may be desired. For instance, you can begin with NO and continue with ether; or administer chloroform, and, in the event of signs of syncope, add a fluid drachm of ether or alternate one with either of the others as may be thought proper. Besides the above it possesses the following advantages:—1. A free influx of air and free outlet. 2. A



good indiarubber cushion attached to the base, so as to fit any kind of face. 3. The use of plates or diaphragms (represented by dotted lines) turned up on the free edge so as to prevent the anæsthetic fluid from dropping down on the patient's face, of which the lower one serves to prevent the reinsufflation of expired air and directs it to the outlet, whilst the upper and middle ones are so placed as to receive the inhalant in any position of the patient and diffuse it over as broad a surface as possible for volatilisation, which is also accelerated by the warmth of the hand of the administrator. 4. Either of the funnels can be used according to position.

Salisbury, May 12th, 1886. M.B. Lond., F.R.C.S. (exam.)

MERCURIAL FUMIGATOR.

THE accompanying illustration represents a method for treating locally syphilitic sores of all kinds in all situations. Into the iron kettle is introduced about a drachm of calomel, the stopper replaced, and the spirit-lamp lighted. After waiting a few minutes for the kettle to be well heated, on

working the bellows a stream of mercurial vapour can be directed against any desired spot, and a film of metallic mercury will then be deposited over the surface towards which the nozzle of the kettle is directed. The mercury can thus exert a very powerful local action, not merely from its

being in a state of extreme subdivision as it must be when deposited as vapour, but as it is just free from its combination when it is in the nascent state. This mercurial [illegible] may be used for primary sores, condylomata, tertiary ulcerations, &c.

W. H. FENTON JONES, M.D.

Brook-street, Grosvenor-square, W.

MODIFIED BEAUFORT LEG.

THE chief object of this modification of the Beaufort leg is the praiseworthy one of placing an artificial instrument within the reach of those who cannot afford the more expensive appliance. The sample that has been submitted to our judgment appears to possess all the necessaries for a useful and artistic artificial limb. It is light in weight, has practically all the advantages of its prototype, and its strength is guaranteed by the presence of long lateral steel splints worked into the leathern substance of the appliance. The instrument, which is manufactured by Mr. Schramm, of Princes-street, Cavendish-square, should therefore prove of great durability. The cost, ranging from £3 10s. to £4 10s., is considerably less than that of the original.

"GUNTHORPE" NATURAL MERINO HOSIERY.

THE increased attention which is now being given to clothing, not only as a means of comfort, but as an auxiliary to health, is one of the satisfactory indications of the progress of sanitation amongst all classes of the public. A new candidate for popular favour as a desirable covering for the body is "Gunthorpe"—a material of which samples in various articles of dress have been submitted to us. The fabric is remarkably light and clean-looking, soft and pleasant to the feel, and is said to be not subject to shrinkage even by washing; but the chief advantage claimed for it is that it is entirely free from any kind of dye, which is often injurious to delicate skins. We have no hesitation in commending "Gunthorpe" as healthful and comfortable wear. The manufacturers are Rogers, Black, and Co., of Nottingham and Aldermanbury; and the agents are Bates, Hendy, and Co., 37, Wallbrook E.C

NEW SANITARY COOKING UTENSILS.

MR. KEEN has designed a ventilating cover for kettles, saucepans, &c., which serves a very useful purpose. By giving opportunity for steam to escape and at the same time preventing the admission of soot, the contents are permitted to boil and gaseous impurities to escape without risk of damage by exposure to smoke. This method not only relieves the cook of the necessity for constant attention to prevent the contents from boiling over, but it is claimed for it that it has a relation to health in promoting their purity. However this may be, there is no doubt that the flavour of vegetable and animal matter is affected by their boiling in a close atmosphere, and Mr. Keen's invention overcomes this difficulty.

THE PREVENTIVE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—The following case is of interest, as showing how syphilis may be prevented by prompt local and general treatment before the chancre has arrived at maturity.

Early in November, 1885, Mr. A. B. C. consulted me for an eczematous affection of the skin, which itched intensely, associated with a few papules and vesicles, the eruption being sparsely scattered over the loins, buttocks, back, and upper arms. An aperient was prescribed, and glycerole of lead applications were ordered, but on Nov. 11th the disease remained *in statu quo*. The aspect of the dermatitis, in part, suggested scabies, but the integument was healthy at those points which are specially prone to become the seat of scabies—viz., the clefts between the fingers and the flexures of the wrists. Moreover, the sarcoptes hominis was not detected microscopically, after careful search in the ordinary manner. The case was further complicated by the recent appearance of a hard, elevated nodule, the size of half a pea, with an inflammatory zone around, situated on the dorsum of the penis immediately behind the corona in the median line. There was a history of impure contact, and nearly three weeks previously the covering of the penis had become abraded during coitus at the precise spot where this small nodule had developed during the past three or four days. The lymphatic glands in both inguinal regions were slightly enlarged. The physical condition of the lesion on the penis led me to consider it a hard chancre not yet arrived at maturity, and, being immature, the prompt destruction of the chancre might arrest the elaboration of the syphilitic virus at the point of inoculation, and its absorption therefrom. Accordingly, the chancre and surrounding parts were freely painted with a solution of hydrochlorate of cocaine, to ensure anæsthesia, and the chancre was destroyed with Pacquelin's cautery. I suggested that Sir William Jenner's opinion should be sought with reference to the skin affection. On Nov. 12th, Sir William considered the dermatitis due to scabies, and that its origin around the loins and buttocks was caused by contagion implanted during congress coincident with the receipt of the syphilitic virus. He suggested the application of sulphur ointment to the affected skin, and thought that the free exhibition of mercury internally was also advisable in order to combat the effects of any portion of syphilitic virus already absorbed. This treatment was fully carried out, and the dermatitis quicky disappeared. The sore on the penis healed under iodoform dressings. The internal use of mercury was discontinued after six weeks, the patient soon regaining his usual health, and none of the secondary manifestations of syphilis have appeared. The success which followed the destruction of the chancre in this case by Pacquelin's cautery, with the simultaneous employment of mercury, leads me to strongly recommend this course for syphilis, *before the chancre has arrived at maturity*, in preference to the opposite plan adopted by so many—viz., that of waiting for the appearance of secondary manifestations before commencing anti-syphilitic treatment. The use of cocaine is invaluable, as rendering the caustic application painless. I am, Sir, yours faithfully,

CHAS. E. JENNINGS, F.R.C.S. Eng.

Park-street, Grosvenor-square, W., May 22nd, 1886.

THE LANCET.

LONDON: SATURDAY, JULY 17, 1886.

THE Commissioners in Lunacy having been pressed by the Home Office to produce their Report for the year 1885 somewhat earlier than usual—that is to say in a reasonable time—have accomplished this feat by the postponement of certain of their tables until next year. The Report, as issued, opens with what we must assume to be a tribute to the memory of Lord SHAFTESBURY, but the biographical sketch is meagre, even for an official notice, and the expressions of appreciation and regret have neither elegance nor eloquence to recommend them. However keenly the Board may feel the loss of its late Chairman, it is clearly not so overwhelmed by affliction as to be incapable of making political capital out of the event. The recollections of Lord SHAFTESBURY most cherished at Whitehall would seem to be those which relate to the opinions he held and the steps he saw fit to take as an opponent of lunacy law reform. Except in so far as it may be convenient—or not inconvenient—to the Board that the existing statutes affecting the custody of lunatics should be modified in a few quite unimportant particulars, the Commissioners are stoutly antagonistic to any change, and they look upon the views and acts of their late Chairman as so much material with which to carry on the war against those who would reconstruct the entire system, bringing it into harmony with the needs and interests of the insane and the sane as they stand related in the general as well as the asylum population. The spirit of red tape and officialism is rampant in the Fortieth Report of the Commissioners, and even more demonstrative than in the reports which have preceded it.

The number of lunatics known to the Commissioners on January 1st, 1885, was 79,704; the number recorded for 1886 is 80,156, an increase of only 452, although the estimated growth of the population has been from 27,499,041 to 27,870,586, or 371,545, so that the "increase of lunacy," as far as the Commissioners are informed, amounts to about 1 in 823, the total proportion of known lunatics to population being about 1 in 349. As to the details of this aggregate number, the Commissioners say: "The total number of lunatics on January 1st last—namely, 80,156—was composed of 7792 of the private class (3968 males and 3824 females), 71,663 paupers (31,586 males and 40,077 females), and 701 'criminals' (533 males and 168 females)." The particulars of the change of numbers they give as follows: "These figures show, as compared with January 1st, 1885, an increase of 41 (18 males and 23 females) of the private class, an increase of 448 (253 males and 195 females) among the paupers, and a decrease of 37 (23 males and 14 females) in those classed as 'criminals.' The total increase of the year, 452, is much below that of any of the preceding twenty-seven years, to which these returns extend." This should dispose of the notion that there is an increase of lunacy. The notion has been preposterous from the outset. The institution of a system of classification and record in relation to the insane has resulted, as it was likely to result, in gradually bringing the unsound of mind under the notice of the public. Many circumstances have conduced to make this work progressive, and there has consequently been an increase of registered lunatics; but we see no reason whatsoever—and we have never discovered any reasonable ground—for supposing that the actual number of occurring cases of insanity has increased year by year more rapidly than the population. The ratio per 10,000 of total lunatics to the population, as given in the Commissioners' table for 1859, was 18·67. This ratio of known lunatics has steadily increased, until in 1885, last year, it reached 28·98. This year it is 28·76, a fraction lower; yet there has, we maintain, been no increase of occurring cases, the apparent increase being due to the more extended recognition of lunatics and to the fact that their lives have been prolonged by more humane and careful treatment, so that the same inmates of asylums are counted in a larger, and increasing, number of annual returns.

There is nothing to note in the Report just issued beyond the facts that in the county and borough asylums the recovery rate has slightly increased, being 2·4 per cent. above the average rate of the previous ten years, and that the proportion of deaths to the daily average number resident is rather less than the average of the previous ten years. For the rest, beyond irrelevant remarks antagonistic to the several Bills which have been brought in with a view to remodel the laws affecting lunatics, and to afford better safeguards against the confounding of eccentricity or delirium with insanity which renders [redacted] liable to be placed under treatment as lunatics, the Commissioners content themselves with the recital of statistical and general facts. When, if ever, the obstacle to much-needed reform is successfully overcome, the reports of a Commission acting under conditions more consonant with the public welfare and conducive to the medical treatment of the insane than those which exist may be of higher value and interest.

IT may be well to revert for a few moments to the question of Direct Representatives and the election of them under the conditions of the Medical Act recently passed. The more compact and correct the general ideas of the profession on this subject the better will be the result of the election which is to take place about November. A little more discussion before proceeding to select persons is to be encouraged for several reasons. The duty to which registered members of the profession will shortly be called is an entirely new one. It is one in which they have had no previous experience, and in reference to which there are no precedents. Registered medical men are a busy, preoccupied body, consisting of 25,993 persons. For this purpose there are no organisations in the profession. There are associations and societies of various kinds, but not for the purpose of promoting such elections as are contemplated under this Act. Nor would the profession like any association to assume a caucus function, and dictate to it the selection of persons; and yet it is evident that without some concerted action in the different parts of the kingdom much time and influence will be wasted, much disappointment caused, and possibly much discredit accrue to the principle of direct representation. There are many critics who have hitherto been no friends to direct representation,

and who have always declared that the election by vote would be an unsatisfactory and undignified proceeding. The strength of this feeling in quarters where better things might have been expected is almost incredible. It is of great moment that it should receive no confirmation in the coming election.

We have, in a previous article, discussed the kind of duties which, under the sharp limitations of an Act of Parliament, the Council has to discharge. We need only now mention them. It has to supervise medical education, to inspect or visit medical examinations, to issue from time to time the British Pharmacopœia, to keep a correct Register, and occasionally to sit in judgment on registered practitioners "accused of infamous behaviour in a professional respect."

One thing ought to be kept in mind—the fewness of the Representatives required by the Act. The 17,109 practitioners of England can only choose three representatives, the 4703 practitioners of Scotland one, and the 4186 practitioners of Ireland one. Five persons to represent 26,000 is a small number, and, within reasonable limits, the fewer the persons selected and nominated by the profession the better. It is of no use scattering votes over a promiscuous number of candidates unlikely to be elected. Two or three great points, it seems to us, should guide the profession in their selection.

First it seems desirable that a great community like that of England should [illegible] something like a territorial representation. The great district of the North of England, of the Middle, and of the South or Metropolitan district, might fairly expect to carry, respectively, a representative of their own selection, and to this end should take prompt and combined local action. How are men in London to judge for the men of Newcastle-on-Tyne, and *vice versâ*? We adhere strongly to our view that the candidates should be representative of the body of the profession. The consultant class, the official members of universities, and medical corporations are represented already, and over-represented. All the wisdom and counsel to be got from them is already secured. The election of such members of the profession as direct representatives would seem to us a mistake of the first order. What is conspicuous by its absence in the discussions of the Council is the contribution of men who do the hard work of the profession, who know by experience the weak points in our medical educational system, in the Register and in the Pharmacopœia, and who may be trusted to maintain the honour of the profession.

THE lecture on Ataxic Paraplegia delivered by Dr. GOWERS last session at University College Hospital is a model of what a clinical lecture should be; and as it deals with a disease which has not yet received at the hands of the profession the attention to which its frequent occurrence entitles it, we propose to indicate its chief features, whilst recommending its detailed study in the pages of the last two numbers of THE LANCET.

A good gait is characterised by the exhibition of a certain amount of force and a certain degree of harmonious action of the muscles concerned in walking. Ataxic paraplegia, as its name implies, spoils both the power and the co-ordinate action of walking. On the one hand it is allied to locomotor ataxy, on the other to paraplegia; but it is not a simple combination of the two diseases, for it differs in some features from simple paraplegia, and still more remarkably from tabes dorsalis or locomotor ataxy. Though the development of incoördination separates it sharply from paraplegia, still the number of differences between it and tabes dorsalis is perhaps the most characteristic fact. The prominent feature of the etiology of tabes dorsalis is the very frequent history of syphilis; this is wanting in the causation of ataxic paraplegia. Like so many of the chronic diseases of the spinal cord, we find "cold," concussion, and mental distress, with over-exertion, playing a large share in the chapter of antecedents. But the real causes mostly elude detection, though it is very probable that the nervous protoplasm of affected individuals never was in that vigorous state of health which is the possession of the bulk of mankind. The clinical course of the majority of cases is one of a very gradual, not to say insidious, kind, and consists in the concurrent development of the two symptoms, weakness and unsteadiness, mostly manifested in the lower extremities. "As soon as the patient is conscious of weakness he is conscious also of unsteadiness." At first sight the patient looks as if he had locomotor ataxy, but an examination of the knee-jerk gives this appearance an active denial, for instead of WESTPHAL'S phenomenon, the knee-jerk is increased, and, what is more, a marked foot-clonus may be obtained, and even also a clonus of the rectus femoris muscle. This exaggerated state of the "myotatic irritability" gives the affection its resemblance to spastic and simple paraplegia. But it is not in the state of the reflex actions alone that differences are to be found, for there exists a remarkable absence of those sensory symptoms which make the clinical picture of tabes dorsalis what it is. The "lightning-pains" are as dominant in the clinical history of tabes as they are inconspicuous in that of ataxic paraplegia; and the same holds good of the other sensory phenomena. The superficial reflexes, as from the sole of the foot, are also present and excessive in the great number of cases. Again, though it is common to note absence of the reflex action of the iris to light in tabes, the "Argyll-Robertson" pupil is seldom present in ataxic paraplegia.

"As the disease increases the muscular power becomes more and more impaired, usually without much increase in the incoördination, which sinks into the background as the paralysis increases, and the patient has to have recourse to supports which at the same time afford him guidance. The increased myotatic irritability continues; stiffness and rigidity develop as its consequence. Thus the aspect of the patient comes to be that of spastic paraplegia, the feet drag as the patient walks, shake from clonus when he stops, and the legs are hauled forwards with visible effort at each step." Those who know most of the mode of gait in disease will recognise the hand of the master in this description.

In the absence of the various crises of the different viscera so much associated with tabes we have another difference in ataxic paraplegia; this goes side by side with the general want of sensory phenomena.

The prognosis is, on the whole, less distressing than the general run of spinal diseases, but chiefly in the circumstance

that the affection has little tendency to cause death, and progresses in so gradual a fashion.

The pathology of the malady possesses several features of considerable interest. The anatomical distribution of the lesion is suggestive of many problems in the physiology of the spinal cord. The sclerosis or chronic degeneration occupies the lateral and posterior columns. The disease of the lateral or rather pyramidal tracts may be held responsible for the weakness, and that of the posterior for the ataxy. But the whole story is not so simple. As the clinical course shows and the anatomy corroborates, we have not a simple mixture of tabes dorsalis and spastic paraplegia. In the first place, the sclerosis is not so marked in the postero-external column as it is in locomotor ataxy, and the lesion is much less evident in the lumbar region. Moreover, there is not that strict limitation to the different "systems" of the cord. In the lateral columns the sclerosis is not accurately mapped out by the pyramidal tracts, for the lesion usually extends in front of and to the inside of these; it may even involve the direct cerebellar tract.

The mechanism by which the coördination of muscular movements is brought about has been considerably elucidated by the study of tabes dorsalis and ataxic paraplegia. The facts connected with these two diseases also show that this mechanism is probably of an even more complex nature than many of us may have been inclined to suppose. The matter, indeed, is too complicated for a full discussion of it here. Briefly, we may say that Dr. GOWERS believes that the principal agent in the production of the ataxy of tabes dorsalis is disorder of the true sensory nerves of muscles which have been shown to exist by TSCHIRJEW. The evidence on this point is very strong. We may have all the symptoms of tabes dorsalis when the cord is healthy and the peripheral nerves alone are diseased. Further, the symptoms of ataxy may exist in perfection when there is no defect in the cutaneous sensory functions. Therefore the ataxy must be due to disease of the sensory nerves of muscles. "It is probable that a very slight affection of these nerves abolishes the knee-jerk, a greater degree causes ataxy, and a still greater degree is required to render the muscles insensitive to pressure and tension." It is thought likely that disease of the posterior median columns may cause ataxy by preventing the proper transmission of the guiding impulses to the cerebellum; for the nucleus in which the fibres of this column end is in close communication with the cerebellum. Moreover, as Dr. TODD believed, the posterior columns probably contain short fibres connecting the posterior grey matter at different levels, and disease of these may also impair coördination. The theory that muscular anæsthesia was the chief cause of incoördination in tabes was advanced thirty years ago by Dr. RUSSELL REYNOLDS.

To return to the explanation of the weakness of ataxic paraplegia. It seems that this symptom cannot always be explained by the amount of sclerosis in the lateral columns. Dr. GOWERS is the author of an ingenious hypothesis which may throw light on this and cognate matters. He believes that the terminations of the pyramidal fibres in the grey matter of the cord may be compared in many ways to the terminations of the motor nerves in muscles; that there may be a kind of "motor-plate" in the ending of what he calls the upper motor segment. These terminal ramifications are supposed to act as local inhibitory centres. As this ramification is at the furthest possible point from the source of nutrition (i.e., the large nerve cells in the motor region of the cerebral cortex), it is reasonable to suppose that, in the event of a defective nutrition of the said source of trophic influence, the most distant portions of the pyramidal fibres would feel the defect first and most. If such an event occurred, then the local inhibition would cease, and weakness of voluntary movements with exaggeration of the myotatic irritability would occur. Possibly this is the explanation of long-lasting cases of hysterical spastic paraplegia that ultimately recover. The hypothesis will also serve to elucidate those cases of genuine ataxic paraplegia in which the sclerosis is almost absent from the lateral columns; for we may then imagine that the termination of the pyramidal fibres in the grey matter is degenerated.

The differential diagnosis of ataxic paraplegia has to be made from tabes, spastic paraplegia, hereditary ataxia, focal myelitis with its consequences, and tumour of the middle lobe of the cerebellum. Enough has been said to show how the first two may be differentiated; hereditary ataxy presents no knee-jerk, but nystagmus and some defect of articulation; whilst its onset in earlier life and in several members of the same family are distinctive features. From the fourth condition, in the nature of things, the diagnostic problem is of the greatest difficulty, and Dr. GOWERS thinks that the regressive tendency of myelitis, as contrasted with the progressive character of the lesion in ataxic paraplegia, is the chief means of distinction. The common accompaniments of cerebellar tumour should prevent any mistake on this score.

THE Town Council of Gravesend have unanimously decided not to build a hospital for infectious diseases on a site which they recently acquired for that purpose at a cost of £700. And they have taken this step in the face of a report from their own officers that their existing wooden hospital is so dilapidated that it had probably led to fatal results in some patients admitted, and that it is not worth repair. The real ground of objection to proceed is because, after certain conferences with the Local Government Board, the estimated cost has risen from £3500, which the Mayor regarded as sufficient, to about £5000; and a strong feeling in the direction of local self-government having influenced the members of the Town Council on the occasion in question, the intervention of the Central Authority was resented, and the scheme was abandoned. Such a result is very much to be regretted, and this especially in the case of Gravesend, lying as it does at the entrance of the great port through which disease may so easily make an entrance from abroad. And not only so, but Gravesend has already had experience of what it is to be unprepared to deal promptly with cases of imported infection.

But the main question to be considered is that of the intervention of the Local Government Board in such matters. As to this, we cannot but think, from a perusal of the proceedings of the Town Council, that some misapprehension exists. There is absolutely no reason why the Town Council of this or of any other town should not build and equip an infectious diseases hospital quite independently of any interference on the part of the Central Authority; although we are

bound to admit that, having regard to the experience possessed by the officials at Whitehall on this subject, the money of the ratepayers would, apart from conference with those officials, not be likely to be spent in the most approved fashion. It was Gravesend itself that sought the intervention of the Local Government Board when they asked that department to take part with them in the proceedings necessary for the raising of a loan to defray the expenses of a hospital. How far it may be desirable for a Central Authority to enable a local authority to secure money for certain specified purposes, without inquiring how that money is to be spent, is a question which may admit of more than one answer. But if there is any justification for a refusal on the part of the Central Authority merely to act as a medium for securing a loan for the local authority, without regard to the method in which it will be applied, it is essentially in the case of hospitals for infectious disease that such a refusal should be made. A vast amount of mischief has been done by infectious disease hospitals, and this especially in the metropolis, where those institutions have been erected by the aid of public loans, and the Local Government Board have learned through their medical staff that there are many dangers, in excess of those hitherto contemplated by sanitary authorities, which have to be avoided. And unfortunately these dangers can only be properly avoided at a cost exceeding that which has heretofore been regarded as sufficing for such hospitals. A lessened number of patients per acre, an increased distribution of buildings over the site, a comparatively wide zone between the hospital buildings and its boundary wall, are all needed in the interests of the community whom it is intended to protect against infection; and these and other similar requirements cannot be ignored by the Local Government Board when their co-operation in the erection of an infection-hospital is asked. But we have heard of recent cases in which, whilst these points have been carefully attended to, no objection whatever has been made to a sanitary authority making only a first instalment of hospital provision; and it seems to us that if Gravesend be really prepared to spend some £3000 on hospital buildings, there ought to be a means by which this expenditure may be made to provide at least a part of such a hospital as will be free from any medical or other objection. On this basis we hope the subject will be reopened; and if this be done, we have no doubt that the district can be provided with a most useful, though not a complete, amount of accommodation for the isolation of the infectious sick, and the consequent protection of the inhabitants of Gravesend. If the Town Council still wish to be free from all interference in the matter, they have only to erect their hospital out of current rates; but in view of the experience of the metropolis, we would counsel them not to proceed in this direction without at least studying the effect which other hospitals have had over a somewhat wide area when those buildings have been used for the isolation of cases of small-pox.

MR. SAVORY'S re-election to the presidency, while generally looked forward to, came as a surprise to many, on account of the well-known objection of the Council to depart from custom. We must congratulate the Fellows and Members on this evidence that the Council is at last waking up to a proper sense of its own dignity, and to the feeling that the highest honour which the College has at its disposal is no longer to be bestowed on whomsoever happens to be the senior member of Council who has not passed the chair. This interference with routine, however, is sure to press harshly on someone. Mr. SAVORY'S re-election will appear somewhat in this light to Mr. WOOD, who, in the ordinary course of events, would have succeeded to the honour of the presidency. No disrespect of any kind could have been intended to the senior Vice-President, Mr. WOOD; neither Mr. SAVORY'S re-election nor the election of two new Vice-Presidents for the current year should be regarded otherwise than as a determination on the part of the Council, at length, to break with an old and undignified tradition. We trust the practice will be continued, and thus the Council will always have a certain number of past vice-presidents from among whom to select the gentleman who promises to make the best president. We cannot but hail these changes with satisfaction, as harbingers of reforms to come, and as the commencement of a more enlightened policy on the part of the Council of the College.

MR. MACNAMARA'S resolution "that, in pursuance of the resolution of the Council of the 9th April, 1885, the Committee on the Mode of Election to the Council and on other matters relating to the Charters and Bye-laws of the College be requested to report, with as little delay as possible, on the steps taken by them in reference to the preparation of the new sections required in the charters and the formulæ for new bye-laws to give effect to the resolutions of the Council respecting them," we are pleased to find, was carried. This will bring into renewed activity the Associations of the Fellows and Members respectively, each anxious to secure a fair representation of their own views and interests in any new charter and bye-laws which may be enacted. The Fellows have already drawn up their suggestions and recommendations, and these have been discussed several times in our columns. It now only remains for the Members to do the same. Let us recommend moderation on the one hand and expedition on the other. It would seem very desirable that a further public meeting of the Fellows and Members at large should be held to consider these recommendations, and to learn exactly what the Council of the College proposes to do before application is made to the Privy Council.

The present is the Jubilee Year of Her Majesty the QUEEN, and will doubtless bring some signal honour to the College. No time could be more propitious, therefore, for the introduction by the Council of wise and liberal reforms into the charter and bye-laws of this Royal College. It is much to be wished that whatever changes the Council desire to make will find favour with the entire constituency, and will secure unanimous support. We can only hope that such changes as may be enacted will be conducive to the general advancement of the College, and of the art and science of surgery.

WE have read with much regret a correspondence in *The Times* which has arisen out of the occurrence of some cases of diphtheria in the Charterhouse School at Godalming, and the action of the school authorities in the matter. From the letter of Mr. CARRITT, the father of one of the boys in the school, it appears that his son was very properly directed by

his house master to inquire whether there would be any objection to his going home for the usual Saturday to Monday exeat, as there had been some cases of measles in the house. Consent having been given, Mr. CARRITT learned from his son that in addition to the measles there had been two cases of diphtheria. Doubtful of the accuracy of this report, the boy's mother wrote to the house master for information, but received no answer to her letter. Hearing from her son on his return to school that one of the boys had died, she wrote again, but with no better result. Naturally dissatisfied with this, Mr. CARRITT and his wife went to the school to make personal inquiries, when they ascertained that there had been nine cases of diphtheria in the school, that one boy had died in the house in which their son was placed, and that there was another boy in it recovering from the same disease. With natural anxiety for his son's safety, Mr. CARRITT applied to Dr. HAIG-BROWN for permission to withdraw him temporarily from the school, but was informed that if he did so the boy would not be allowed to return. Acting on the opinion of his medical adviser, Mr. CARRITT felt it his duty, notwithstanding this intimation, to take his son home, and then wrote to Dr. HAIG-BROWN to ask whether he really intended to carry out his threat of not permitting the boy to return, and received a reply that he could make no other answer than that already given. Mr. CARRITT then wrote to *The Times*, giving a temperate account of the affair and protesting against the head master's arbitrary proceeding. This drew a letter from Dr. HAIG-BROWN to the editor, with a view to relieve any anxiety which might have been created, in which he stated that "during the last two months we have had two cases of diphtheria and seven other cases of throat ailment with diphtheritic tendency. To our great sorrow, one boy died of the consequences of diphtheria at a time when we supposed his recovery to be assured. No fresh instance of such illness has occurred since June 13th, and there is none such in the school now." At the same time he declined to answer anything in Mr. CARRITT's letter referring to his conduct. We regret to think that Dr. HAIG-BROWN has taken up a very false position in this matter. As head master he must reign supreme in the school; but this does not relieve him from the responsibility of acceding to reasonable requests on the part of parents when the health, possibly the lives, of their children are concerned, nor from the obligation to give them some explanation of his reasons for adopting so unusual and high-handed a course as he seems to have done on the present occasion. We think also some explanation is required of the discourtesy on the part of the house master in not answering the two letters addressed to him by the boy's mother. In connexion with this correspondence several important collateral questions arise. We have no information as to whether the diphtheritic illness was confined to one house or was spread generally over the school; nor whether any, and, if any, what steps were taken to secure the separation of the sick from the healthy. It would also be important to know what has been done with a view to trace the cause of this outbreak, and what measures are proposed to prevent the recurrence of such a disaster. The head master may rest well assured that the best course to relieve the anxiety of parents and restore the confidence of the public in the school will be to make a clear statement regarding the extent to which disease has prevailed among the boys, the measures which have been adopted to prevent its spread, the steps taken to ascertain its cause, and the course already pursued, or in prospect, to improve the sanitary condition of the establishment. We cannot but feel that when the question was very properly asked with regard to the return home of the boy from a house in which there were cases of measles, the fact that the existence also of diphtheria was concealed is very unsatisfactory and calls for some explanation.

Annotations.

"Ne quid nimis."

THE MINUTES OF THE GENERAL MEDICAL COUNCIL.

NOW that the profession is to have five voices in the Medical Council it may be expected to show more interest in the proceedings of this body. A volume of Minutes—the twenty-third—has just been issued. It is one of more than usual interest, and conveys more than the ordinary information as to the ways of the Medical Council and of the bodies which are responsible for granting degrees. The reports of the Visitations of all the universities, and of the answers of the universities to the criticism of the Visitors, are contained in one of the appendices of this volume; and another appendix contains the second report of the Statistical Committee, furnishing an instructive summary of statistics regarding medical students registered as commencing their medical studies in the quinquennium of 1871-1875. The volume can be purchased either at the office of the General Medical Council, 299, Oxford-street; or from the publishers, the Messrs. Spottiswoode.

EXTENSION OF THE CHOLERA EPIDEMIC.

CHOLERA has, during the past week, made considerable ravages in Southern Italy, the daily number of cases and deaths in the province of Brindisi having steadily risen from some 30 and 5 respectively to about 150 and 50. During the four days ending July 13th the total cases in the province had amounted to 420 and the deaths to 149. Of these attacks the largest number occurred in the town of Francavilla Fontana, where, during the same period, 233 cases and 99 deaths took place. Latiano also has suffered severely, 138 cases and 56 deaths having occurred there. Amongst other places attacked in the province are Brindisi itself, with 30 cases and 14 deaths, and Erchie, with 20 cases and 5 deaths. The most southern portion of the kingdom as yet infected would appear to be San Vito, where in three days 44 cases and 11 deaths took place. Somewhat higher up the coast than Brindisi, the disease is stated to have made great havoc at Mola di Bari, but no statistics are forthcoming as to this place. In the northern part of the kingdom Venice still suffers, although no material increase has as yet taken place there, the daily fatality being limited to one or two only. At Codigoro, in the immediately adjoining province, the fatality is increasing, and in the four days ending the 13th inst. 38 cases and 9 deaths were reported to have occurred. So, also, occasional cases have occurred at Trieste and at Fiume; but no extension into the interior of the Austro-Hungarian Empire has taken place. Returning again to Italy it is stated that isolated cases have been reported from the provinces of Bologna, Verona, Padua, Modena, and Vicenza. It is not easy to place a proper interpretation on such rumours, for whilst in an early stage

of an epidemic there is almost invariably a great tendency to hush up the first isolated attacks, there is after a time a similar tendency to regard every case of fatal diarrhœa as having been due to cholera. It is, however, satisfactory to know that amongst the Government officials who have visited the cholera-infected districts is Signor Morana, Secretary-General of the Department of the Interior, who has already acted as the Government historian of the epidemics of 1884 and 1885, and who has shown that his main desire is to place on record a faithful account of the occurrences of cholera in Italy, both as regards their statistics and as to the attempts that are made, whether by quarantine restrictions or otherwise, to stay the progress of the disease.

THE ETIOLOGY OF PNEUMONIA.

THE causation of pneumonia, notwithstanding its apparent simplicity in a great many cases, is in many more so obscure that every rational theory as to its origin must still possess a certain interest. It would be strange if sepsis, which is triumphant in various associated forms of illness, had no influence here, and we are accordingly prepared to find that it has. Even if those varieties of the disease which are connected with tubercle or with insidious catarrhal processes, and are not at first pneumonic, be excluded, the history of continued fever affords examples of germ development, which is first revealed in an inflamed lung, or is there engrafted during convalescence. In apparently simple cases due to chill, moreover, the share of malaria as a depressing precursor is not always easily defined. It must, however, be owned, after due allowance for every such morbid agent, that by far the commonest cause of acute lobar pneumonia is external cold. This theory, the truth of which is often self-evident, will best explain why strong and weak subjects alike are apt to be suddenly seized with inflammation of the lung, and why the prevalence of this disease bears a close relation to changes of the weather and is compatible with an atmosphere of great purity. Some who seem to favour an obscurer theory of chemical influence regard ozone as in some way directly responsible. Such, at least, would seem to be the implied meaning of statistics quoted by Dr. Draper, of New York, in which he couples an epidemic of pneumonia in that city with a high percentage of ozone in the air. We confess that we cannot trace any clear connexion between this supposed cause and the effect. If, however, we take the excess of ozone to indicate, as it well may, a fluctuating temperature with prevailing stormy winds, we have here conditions which will account for much inflammatory disease. This is probably the true version of the ozone theory. A theory which has been suggested,—not, we believe, by Dr. Draper, that ozone-pneumonias are due to ozone-fed germs, appears quite untenable in view of the fact that there is no better germicide than oxygen.

ELECTRIC CHARTS.

ELECTRICITY is of most use in diagnosis. To those who are in the habit of taking accurate electrical observations the possession of charts would prove of considerable value. Hitherto, in an ordinary way the number of facts to be recorded has been so limited that it has scarcely been worth while to employ electric charts. Nor is this state of things likely to change unless further important information of diagnostic or therapeutic value should be forthcoming; we cannot, therefore, predict for Dr. Leslie Phillips' neat, elaborate charts any very extensive employment. Though electric charts are not destined ever to become so generally useful as temperature charts, yet we cannot but think that any means which would facilitate the registration of observations are things to be desired.

ANATOMICAL AND MEDICAL KNOWLEDGE OF ANCIENT EGYPT.

THE surviving fragments of the early literature of Egypt are mainly of a religious character; but this is not to be wondered at, for the genius of the people was essentially religious, and their doctrine of the future state leavened their national life in almost every particular. To them the body was an integral part of the immortal humanity; therefore it could not be permitted to turn to decay, but had to be preserved from corruption that it might be a fit receptacle for the soul to dwell in through eternity. Their treatment of the body was thus dependent on their belief of its relation to the soul, and this, we learn from their religious writings, was a relationship of eternal independence. To secure perpetual preservation the body had to be properly embalmed, the cavities opened and subjected to the action of antiseptics. Although the body was sacred, under the special protection of the god Thoth, though each part was under the guardianship of a special divinity, yet this sacredness did not preclude careful inspection and the processes necessary for preservation, for all parts had to be perpetuated. Embalming was a religious rite, to be performed by the priests of the Cultus; and the historian Herodotus, has preserved for us what is doubtless a substantially accurate account of the different methods whereby it was done in the later times in which he lived. The organs removed from the bodies of persons of the better classes were not returned into the body, but were preserved in vases of alabaster or stone, surmounted by the heads of the four divinities of Hades, the sons of Horus and Isis. The vessel which contained the stomach and colon bore the human head of Amset; that which held the lungs and heart was under the protection of the jackal-head of Tuaut-mutef; that which contained the small intestine was beneath the baboon-head of Hapi; while the liver was guarded by the hawk-head of Kabhsenuf. During the ascendancy of Greek influence in Egypt, Alexandria earned the reputation of being the chief school of anatomy and medicine in the world. Erasistratus, who lived in the days of Ptolemy Soter, B.C. 285, was an anatomist of such enthusiasm, that he and his disciples receiving from the king criminals condemned to death, "Vivos inciderint considerarintque etiam, spiritu remanente, ea quæ natura ante clausisset, eorumque posituram, colorem, figuram, magnitudinem, ordinem, duritiem, mollitiem, lævorem, contactum, processus deinde singulorum et recessus et sive quid inseritur alteri sive quid partem alterius in se recipit." But this Alexandrian school, although upon Egyptian soil, was essentially Greek in spirit; even Herophilus had learned some of his anatomy from Praxagoras of Cos, although, as the anatomy of the earlier Greek school was originally derived from Egypt, it was but returning to the mother country the traditions of culture derived therefrom. It was in Egypt Democritus of Abdera studied, and so was fitted to teach anatomy to Hippocrates, the father of medicine. The three pithy and graphic letters on anatomy (which are extant), which it is supposed Democritus sent to Hippocrates may well have been the result of his Egyptian training. At a later period, it was at Alexandria that Galen pursued his study of anatomy under Heraclianus, and the anatomical school of Alexandria survived until the Mohammedan invasion of Amru in A.D. 640. That much even of the earlier Greek medicine, anatomy, and pathology was derived from Egypt we learn both directly and indirectly. Most of the vegetable drugs in use in Greece were natives of Egypt; and Galen, speaking of one prescription called Epigonos, tells us that it was obtained from the adytum of the temple of Ptah, at Memphis. He quotes it, and other Egyptian prescriptions from the book Narthex, written by Hera of Kappadokia. Medical colleges of far greater antiquity than that of Alexandria existed in the priestly

schools of Memphis, Heliopolis, Sais, and Thebes. These were much more faithful exponents of the purely Egyptian system of the art of physic. Of the ancient medical literature of Egypt, two nearly complete treatises are still extant, and six or seven fragments of others. These vary in date and in perfection. The most complete are the Papyrus Ebers and the Medical Papyrus of Berlin. The fragments which are noteworthy are:—The British Museum Papyrus, formerly the property of the Royal Institution, the Papyrus VI. of Boulaq, the Magical Papyri of Turin and Paris, the Coptic Medical Manuscript in the Borgia Library, and the Greek Papyri 383 and 384 of Leyden. In a paper read at a recent meeting of the Royal Institution of Great Britain on the Medical Knowledge of Ancient Egypt, of which the above is a summary, Professor Alexander Macalister, M.D., F.R.S., stated that he hoped soon to be in a position to publish a detailed and critical study of this medical literature, a work for which few are better qualified.

THE MEDICAL CARE OF BOYS AT PUBLIC SCHOOLS.

THE death of one of the scholars at Charterhouse School from the consequences of diphtheria at a time when his recovery was supposed to be assured is a fresh illustration of what for several years past we have endeavoured to point out. There are grave defects in the medical care of sick boys at our public schools. At Charterhouse, as at other schools, the most simple and ordinary rule for the protection of the healthy by isolation of the infectious sick appears to be set at nought. The Association of Medical Officers of Public Schools has framed a series of rules for the protection of schools from the introduction of infectious illness from without; but the same rules, when required to be brought into operation for the protection of the public—and the relatives of pupils in an infected school—seem to be to a great extent ignored. The head master at Charterhouse, whose son, it would appear, is the medical attendant at the school, states that "he does not care to answer the charges so far as regards his own conduct." We have before represented that whenever a death takes place at a public school there should be a full and impartial inquiry, not only into the cause of death, but into the methods adopted to guard against the fatal illness. Painful as it would be to the parents of the deceased scholar at Charterhouse School, it is to be hoped they will have sufficient courage and fortitude to call for an investigation by inquest into the cause of the death of their son at a time when "his recovery was supposed to be assured," as the head master asserts, and he was well enough to be among his schoolfellows again.

THE MICRO-ORGANISMS OF ACUTE SUPPURATION.

DR. D. O. KRANTSFELD, who has been engaged in the micro-biological study of acute suppuration in Professor Ivanovski's laboratory in St. Petersburg, states that it is always possible to detect micro-organisms in the pus of acute suppuration, both by means of cultures and by direct observation. Those most frequently met with are staphylococcus pyogenes (aureus, albus, and citreus) and streptococcus pyogenes. The presence and multiplication of micro-organisms in the tissues is, he thinks, the most important factor in the etiology of acute suppuration. They may, however, enter into the organism without setting up acute suppuration, the other conditions regulating this being their number and concentration, and the local and general state of the tissues. Staphylococcus and streptococcus are quite distinct from one another, both morphologically and biologically. In culture media staphylococcus develops quickly and equally well whether air is present or not, whereas streptococcus develops more slowly and is less vigorous; it also thrives better without free access of air, as in the deeper parts of the medium. In the tissues staphylococcus pyogenes develops rapidly, and may be carried along with the blood, while streptococcus pyogenes is more slow in its development, and especially affects the lymphatic vessels. In a large majority of cases of local acute suppuration the micro-organisms gain an entrance by means of external wounds, though sometimes they do not do so; abscesses due to staphylococcus pyogenes are generally situated near the locality in which the micro-organisms enter; those due to streptococcus pyogenes, on the contrary, are found at a distance from the place of injury, along the course of the lymphatic vessels, the lymphatic glands determining the localities of the suppuration. Both the micro-organisms may set up pyæmia and septicæmia, the foci in which staphylococcus is gathered being generally situated in internal organs, tending thus to give the affection more of a pyæmic character, while the collections of streptococci are mostly found about the joints and in serous cavities, thus causing symptoms more of a septicæmic character. At the period of life when the skeleton is growing, staphylococcus aureus has a tendency to find its way to the organisms of locomotion, especially to the bones. Pure cultures of staphylococcus pyogenes introduced into rabbits set up abscesses, pyæmia, septicæmia, and acute osteomyelitis. The suppuration occurring when antiseptic dressings are used must be classed etiologically with ordinary acute suppuration. These remarks apply to acute suppuration only, the examination of the pus from cold abscesses giving different results from that of the contents of acute abscesses.

SLEEP-WALKING.

AN inquest was held on July 9th, at Chester, on the body of a soldier who had died from injuries received by falling from a high window on to the ground. It appears that he got out of bed, opened the window of the room in which he was sleeping, and jumped out. He was accustomed to sleep in a room on the ground floor, and frequently left the room by the window instead of the door. There does not appear to have been any evidence brought forward that he had been known to do so at night, or that he was in any way accustomed to walk in his sleep. A verdict of "Accidental death" was returned. Sleep-walking or somnambulism is explained on the hypothesis that the sleep is partial in its area; portions of brain which are usually involved in the physiological condition peculiar to sleep remain exempt, so that the sleeper exhibits powers which sleep usually annuls. The individual appears to possess an unusual power of calling his muscles generally into activity in response to dream thoughts. Sight in relation to the dream may be good, muscular sense impressions also, but the sleep-walker may be deaf to all ordinary sounds. Hilton Fagge had the opinion "that true somnambulism (at least, when it is not a manifestation of hysteria) has every claim to be regarded as one of the members of the group of paroxysmal neuroses," in which group he includes migraine, epilepsy, paroxysmal vertigo, and paroxysmal insanity. In the attacks of somnambulism the sleeper will perform various acts—get up in the night, perhaps dress, go downstairs in the dark, move something from its place, or do something else quite trivial in character, return to his room, undress, and get into bed again; in the morning, however, there will be no recollection of the occurrence. At other times the walk may not be without danger, and cases are on record where the sleeper has met with a violent death from following the suggestion of his dream. This is of importance from a medico-legal point of view under a con-

tested policy of life insurance, in which it may have been provided that suicide would vitiate the policy. However, as suicide is held to include only intentional killing, could it be proved that the man was a somnambulist, the policy would hold good. The allied condition—that of somniloquy or sleep-talking—is extremely interesting, and there are wonderful accounts given of intellectual feats accomplished by people the subjects of it: abstruse mathematical problems solved, discoveries made, poems written, and long conversations carried on, there being complete forgetfulness on the part of the performer as to the occurrence of the act. In these cases there is not only a partial abeyance during sleep of some functions of the brain, but also an exaltation of others.

ELIMINATION OF MERCURY AFTER HYPODERMIC INJECTIONS AND INUNCTIONS.

THE system of treating syphilis by means of hypodermic injections having been of late largely employed both in this country and on the Continent, any information on the subject of the rate of diffusion and elimination of the mercury thus introduced is likely to prove valuable. An elaborate series of observations on the elimination of mercury by the urine after hypodermic mercurial treatment has just been published by Dr. Sukhoff, "ordinator" in the syphilitic clinic of Professor Tarnovski in St. Petersburg. The preparations used were a solution of corrosive sublimate, a similar solution with the addition of common salt, Bamberger's albuminate of mercury, the same author's peptonate of mercury, Max Bockhart's sterilised "blutserum-quecksilber," a solution of bicyanide of mercury, recommended first by Cullingworth (*vide* THE LANCET, May 23rd, 1874), a solution of the mercurial amide of formic acid, or Liebreich's hydrargyrum formamidatum, an emulsion of calomel, and, lastly, a solution of biniodide of mercury in iodide of potassium. The above solutions were mostly of the strength of 1 per cent., and the doses given usually corresponded to one-sixth of a grain of the salt used. Mercury was found in the urine about five hours after a single injection of any of the above, except the solution of the biniodide, which was not followed by any signs of mercury in the urine until after ten daily injections. During the course of treatment the amount of mercury in the urine gradually increased, but not at the same rate for all preparations. After the conclusion of the treatment the quantity eliminated continued for one or two weeks as great as it had been at the end of the treatment, and then declined, the fall being more gradual than the rise had been. There were no breaks in the elimination, and no difference was found in the quantities eliminated during different periods of the day. The organism gradually and spontaneously freed itself from all the mercury which had been introduced. Where mercurial stomatitis existed a much larger quantity of mercury was found in the urine than in other cases; the author therefore suggests that when stomatitis has been produced much smaller doses should subsequently be administered. The most active of all the preparations employed appeared to be the formamidate, for after a single injection the mercury was entirely eliminated in a couple of days.

Another series of observations on the urinary elimination of mercury has been made by Dr. Michaelovsky, also an "ordinator" of Professor Tarnovski's clinic. Here the form of treatment employed was that of inunction. The observations agree with those of Dr. Sukhoff in regard to the uniform and gradual method in which mercury passes from the system. Several different ointments were employed for the purpose of comparison. Mercury was detected in the urine about twelve hours after a single inunction of half a drachm of ung. hydrarg. cinereum duplicis, which contains fifteen grains of metallic mercury, no difference being observed when the ointment was prepared with cacao butter instead of suet, as is usual. A similar effect was produced in the same time by an inunction with half a drachm of Oberländer's mercurial soap, which also contains fifteen grains of mercury. An inunction of a drachm of the simple ung. hydrarg. cinereum, which contains twenty grains of mercury, was required to produce as rapid an effect on the urine as half a drachm of the two former preparations. Oleate of mercury was also tried in quantities of half a drachm, which contained fifteen grains of the yellow oxide. In this case three inunctions were required. The least active of all the ointments employed was the ung. hydrarg. sublimat. corros., which contains eight grains of the sublimate to the drachm. Here eight inunctions of half a drachm, or even a drachm, of the ointment were required before the urine answered to the test for mercury.

"IDIOTS" IN ASYLUMS.

WE warmly sympathise with the wish that idiots should not be exposed to the evils of contact with the insane. As Dr. Ireland eloquently contended in the address he delivered before a branch meeting of the Medico-Psychological Association at Carlisle in April last, "Imbeciles are generally weak, timid, and imitative. In a single night passed in an asylum for adults they learn practices which they never forget. They are often terrified by the wild words and antics of maniacal patients, catch up the oaths and curses which float about, learn their lowest habits, and imitate their wild movements. Naturally soft and credulous, they sometimes adopt the delusions which their insane companions take the trouble to teach them." All this is freely admitted. Nevertheless, it does not follow upon this recognition of a danger that the safeguard provided must needs be free from all peril of its own. We must confess to a fear that, inasmuch as the line of distinction between "idiocy"—or "imbecility," as it is now loosely called—and lunacy is not clearly drawn, it may happen that young persons who are, or are supposed to be, insane may be placed in asylums for idiots, instead of being subjected to the official scrutiny which, sooner or later, must be instituted as a protection to the insane before incarceration in an asylum for lunatics. It is doubtless most desirable that the greatest facilities should be offered for the separate training of idiots or imbeciles, but this ought not to be made an opportunity for the creation of a way by which weak-minded young persons can—we do not say will—be "put away" without the utmost precautions which the law can enforce for their protection. Dr. Ireland's address, which has just been published, is an excellent one, and we commend it to the attention of our readers as full of sound sense and trustworthy information.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR JAMES PAGET was in his right place presiding over the Jubilee Festival of this Fund. The eloquence, alike of his life and speech, was engaged in a thoroughly congruous duty in urging those who had been more fortunate in our "great unendowed profession to be mindful of those who had been less so. Sir James's chief theory of the want among members of the profession is that it may be entered without much capital. No one fact, of course, will explain why so many medical families come to need the help of such a fund. We may take another opportunity of discussing this. Meantime, let all who can help, do so. Great thanks are due to Dr. Broadbent for his hearty and valued labours as treasurer: £3500 is not a bad result of such good offices. The generous estimate of our profession by dignitories of the two great branches of the Catholic Church was very gratifying.

THE BACILLI OF TYPHOID FEVER.

DR. VILCHUR, who has been engaged in studying the bacteriology of typhoid fever in Prof. Afanasieff's laboratory, and who has published an interesting communication on the subject in the number of the *Vrach* just to hand, finds that typhoidc olonies are generally larger than similar colonies of a non-typhoid character; their colour, also, is a yellowish cinnamon, whereas in others there is no yellow tinge, and, moreover, they are cinnamon under circumstances in which non-typhoid colonies turn of a brown or even of a black colour. In doubtful cases consideration of the symptoms and of the microscopical preparations of the colonies will generally serve to distinguish those of a typhoid origin. Dr. Vilchur made more than two hundred cultivations from the organs of four typhoid patients, and examined the stools of twenty cases about the thirteenth day of the disease. He found that the bacilli multiply more luxuriantly in meat-peptone agar-agar than in meat-peptone jelly. Their breadth seems, too, to depend upon the cultivation medium, the broadest being developed on potatoes at 27° C., and the narrowest in meat-peptone agar-agar at the ordinary temperature of the room, the length ranging from the third of the diameter of a red blood-corpuscle to more than the full diameter. The longest specimens were developed in jelly cultures, and the shortest in agar-agar ones. Peculiar forms were met with after jelly cultures had stood for a considerable time; some bacilli being unequal in width, others having spores at the extremities and taking the stain very badly. Spores that could not be stained were obtained after a potato culture had remained in the thermal chamber at 37° C. for forty-eight hours, or for from fifty-eight to sixty hours at 27° C. When the potato remained for from seventy-two to eighty hours at 37° C. the spores regained the ability to take the stain, and indeed stained better than the bacilli themselves. An excellent stain for the purpose was found to be a solution of rubine in aniline water. In potato preparations kept for from forty-two to sixty hours bacilli were frequently met with presenting entirely unstained portions or vacuoli, the rest being well coloured. The author remarks that the micro-organisms which grow in colonies on plates do not correspond in number with those met with in stools, which implies that peptone jelly and agar-agar are not suitable media for the development of all micro-organisms. The stools of typhoid patients almost always contain typhoid bacilli in greater or less numbers and capable of being multiplied by cultivation. In the present series of researches they were found in sixteen cases out of twenty; in one case of typhus levis and in one of typhus afebrilis the existence of typhoid bacilli was demonstrated quite clearly.

SWIMMING A COMPULSORY STUDY.

THE sad recital of deaths from drowning which have occurred at various parts of our coast during this summer may well impress upon us the need, too little regarded, that every capable member of the community should learn to swim. We have already commented upon this subject, and have gone so far as to advocate the inclusion of swimming as an essential branch of education. Some, perhaps, may think that our view is an extreme one; they may tell us that fatalities from drowning do not, after all, greatly swell the registered death-rate, unless, indeed, we include those due to shipwreck, and that physical education may be regarded as an optional form of training, for which taxpayers would object to become responsible. From such a line of argument we feel obliged to differ. When we consider how great a portion of our population live at the coast, how many of these follow a seaman's calling, to what exigencies even the dwellers in inland districts may be exposed, and are often fatally exposed, by the chances of an occasional sea voyage, or by the customary visit to the seaside, it appears to us at least highly expedient that swimming should be included in the compulsory school course. It must be remembered that the time or trouble involved in teaching this art is as nothing in comparison with that required for intellectual study. The further steps of practice proceed without tuition. Admission to baths is not costly, the habit acquired is never lost, and the gain is invaluable.

MISTAKEN IDENTITY.

A CURIOUS case of mistaken identity, which recalls many others of like nature, was reported last week as having happened before a coroner's jury at St. Martin's Vestry Hall, Strand. The body of a man, aged about fifty, was found drowned near Charing-cross Bridge. A metal box was found in the pocket of deceased, which was identified by the clerks of Messrs. Carter and Co., seedsmen. But more curious still was the testimony of Thomas Kirby, in the employ of Messrs. Carter. This witness stated that he recognised the body as that of a fellow-clerk named Wilson, by the existence of "a peculiarity of two fingers of the right hand." Thus everything tended to warrant the jury in returning a verdict as to the death of the man Wilson, when the latter walked into court, bearing the marks on the fingers by which his identity had been mistaken. We are not informed whether the similarity of the deformity in the two persons was sufficiently marked as to deceive an experienced observer; but, at any rate, there can be little doubt that Wilson would have been "found drowned" though still living, had he not opportunely turned up. It would have been interesting to have watched the sequence of events which would have followed the finding in the coroner's court had Wilson failed to put in an appearance. The case illustrates the value of taking skilled medical evidence in all instances where death has arisen from other than natural causes, and of recording all physical peculiarities in a permanent way—e.g., by plaster-casting or photography. We doubt not that, had the facsimile of the marks on the body of the drowned man been kept for reference, it would have sufficed to show that the deformity differed in essential features from that of Wilson, even if this person had not been forthcoming to astonish the officials and audience of the coroner's court. It has been truly said that the mind is affected more by positive than by negative evidence, and for this reason it is advisable that every effort should be made to establish identity where there is more or less obvious similarity. The standard works on Medical Jurisprudence contain many cases of mistaken identity as regards both dead and living persons, but fortunately there are few where sooner or later the truth has not come to light. Nevertheless, it is of the highest importance that mistakes of the nature of the one under discussion should be detected and rectified before a miscarriage of justice has obtained, or possibly an irretrievable wrong has been inflicted.

THE RISE AND DEVELOPMENT OF NURSING.

UNDER the auspices of the National Health Society a series of lectures on the Art and Development of Nursing have been given by Miss Manson, matron of St. Bartholomew's Hospital, and were concluded on Wednesday last. The lectures have attracted considerable interest, the audiences being large and representative. Miss Manson takes a high view of the duties and responsibilities of a nurse, but insists upon the nurse being the assistant and servant of the doctor, whose eyes and ears she ought to be in the latter's absence. Tracing the history of medicine from the earliest times, she proved by quotations and references to authority that the Romans had hospital tents attached to their armies for the reception of the sick

and wounded. The graphic description of an ancient Musulman hospital at Cairo, the completeness of which was remarkable; a reference to the misery of those who were consigned to the wards of the Hôtel Dieu at Paris a century ago, where the arrangements were so horrible as to cause the leaders of the Revolution to change the name of hospital to hospice; and an outline of the treatment of patients in St. Bartholomew's Hospital at the date of its foundation, were amongst the most interesting and effective points of the first address. Miss Manson also emphasised the fact of the womanliness of nursing as a profession in which the best and keenest sympathies of women are awakened towards the sick and suffering. The patience, charity, and compassion that are aroused in the true woman by a nurse's calling tend to develop the best and highest qualities of her nature. The presence of "tares" in the nursing field, as elsewhere, she said, was greatly to be regretted, but the tendency of modern systems of training was to eliminate all the unworthy at an early period of their hospital connexion, and so to increase the value of nursing by adding to the respect in which nurses as a whole were held by all who have to do with them. Miss Manson certainly did good service to the medical profession and to the cause of nursing by her fearless condemnation of practices which we have had to censure on more than one occasion.

MANURE IN KENSINGTON GARDENS.

THE daily press has rendered good service in denouncing the distribution of the mud taken from the Round Pond over the grass by the side of the flower-walk in the Kensington Gardens. On Wednesday we visited the Gardens, and found that the manure had been spread over an immense area of ground. It lay close to the roadway, both on the Kensington and Bayswater sides. The smell might well reach the houses if the wind blew in that direction. Though at that moment there was a strong gale and no sun shining, we nevertheless noticed an odour of musty decaying vegetable matter. This came from the black mud which had been extracted from the Round Pond, where it had accumulated to a depth of two feet. It is obvious that the Gardens at Kensington cannot be treated as a field in some uninhabited rural district. If the grass is in need of strengthening, this is assuredly the occasion for the application of uninjurious and non-odorous chemical manures. The petty economy implied by the use of the mud out of the pond is utterly unworthy of this great city and of a pleasure-ground surrounded by some of the wealthiest habitations in the world.

ELECTRIC BATHS IN EYE DISEASES.

PROFESSOR DENTI, writing in the *Annali di Ottalmologia*, states that he has found electric baths and douches very valuable in several ophthalmic affections, especially in those which refused to yield to more ordinary methods of treatment. His apparatus consists of a vessel of water placed at a height of two metres above the patient's head, a constant current battery of thirty cells, and a glass or ivory box without a bottom. This box is fitted on to the eye. It contains a metal pipe communicating by an indiarubber tube with the water vessel, from which the box can be filled with water; an efferent non-metallic pipe is also provided. The metal pipe is connected by wire with one pole of the battery, the other electrode being placed on the forehead or crown of the head. The sittings are of from four to six minutes' duration. For baths eight or ten cells are used, for douches twenty or more. No unpleasant effects have ever been observed, the stimulating action being only sufficient to produce a slight degree of hyperæmia. The author finds that the baths are best in deep-seated affections, such as those of the vitreous or of the optic nerve; the douches are useful in more superficial affections, such as those of the conjunctiva and cornea. Dr. Denti tried the electric baths in six cases: four of atrophy of the papilla in different stages, one of disseminated cloudiness of the vitreous, and one of double ulcerative blepharitis. The papillar atrophy was benefited most when it was slightest. In one case of atrophy accompanying disease of the spinal cord, the intra-ocular affection was, or appeared to be, arrested. The patient with the cloudy vitreous was so much improved that, though at first he could scarcely distinguish large objects, after thirty sittings he was able to read ordinary print. The patient with blepharitis was completely cured. The douches were employed six times: in three cases of paralysis of the eye muscles, and in three of exudations remaining after ulcerative keratitis. One of the cases of paralysis was entirely cured, the other two being improved; and in the cases of keratitis the success was most marked, the exudation being completely absorbed.

POST-GRADUATE COURSES IN GLASGOW.

IN a former issue we were able to announce that a series of lectures had been arranged to be held during the ensuing autumn. We are now in a position to give more detailed information to our readers. Professor Gairdner, Dr. Joseph Coats, and Dr. David Newman have arranged together to give a series of lectures and demonstrations, which will be held in the Western Infirmary, and which will be made as practical as possible, being illustrated by cases, museum specimens, and diagrams. The subjects to be taken up are as follows. Professor Gairdner will lecture on the Diseases of the Abdomen, which are somewhat loosely grouped by the Registrar-General under the designation Tabes Mesenterica. Dr. Coats will take up the subject of Phthisis Pulmonalis in certain of its aspects, with reference especially to its etiology and the coincident lesions in other organs. Dr. Newman will discuss some of the Affections of the Kidney for which Surgical Treatment may be required, with special reference to pathology and diagnosis. The first two lectures will be delivered at the Western Infirmary on Friday, Oct. 1st, at 1 P.M. and at 2.15 P.M. respectively. The course will be continued every Tuesday and Friday until Oct. 19th, there being two lectures delivered at each meeting. A syllabus of the course will be published, and may be had on application to Messrs. James MacLehose and Sons, St. Vincent-street, Glasgow, from whom also tickets for the joint course may be purchased, price one guinea and a half.

THE RULING HABIT.

IT has often been remarked that an actor is generally extremely different in character and mood off and on the stage respectively, and that his greatest successes are commonly the result of his greatest efforts. There have been many notable exceptions to this rule, but it is certain that an assumed character may so react on the brain and nervous system as to modify the natural type. Another point of interest is that in the case of performers who develop special facilities of action—for example, acrobats—habit, becoming "organised," is part of the nature, so that even in moods the least consonant with those to which the acts learned are professionally associated the ruling habit may be brought into play and determine conduct. It is not therefore certain that when an acrobat killed himself the other day in a lunatic asylum by throwing half-somersaults until he succeeded in striking his head so as to cause death, he deliberately chose that mode of suicide. It is quite as likely that in a paroxysm of madness the habit dominated. Lunatics are often remarkably insensible to pain.

CAVOUR AND BISMARCK ON STATE MEDICINE.

A LITTLE volume of some seven hundred pages, entitled "La Sapienza Politica del Cavour e del Bismarck," has just appeared under the competent editorship of Signor Filippo Mariotti, the well-known Italian publicist and man of letters. Though primarily designed for the student of politics, the book has a great deal to interest the professional man, and not least the votary of the healing art, dealing as it does with the relations of hygiene to the State, with the right of Government to interfere in professional education, in the food and water supply of the community and in the complex social questions which are brought home to the busy practitioner every day of his life. Signor Mariotti, remembering the saying of Bossuet, "C'est la maxime qui fait les grands hommes," has perused the many discourses of the great Italian and German statesmen with a vigilant eye to those passages in which years of special thought and experience are condensed and crystallised, so to speak, in pregnant apophthegms and memorable sayings; and the result is a volume of inductions and illustrations which cover the whole field of political and public life, and put the reader in possession of guiding principles which, in such crises as that we are now passing through, will be found as valuable as they are opportune. When the tumult and the din of an "appeal to the country" has subsided, and the approach of autumn brings the weary professional man the holiday he has earned, we can imagine few pleasanter or more profitable *compagnons de voyage* than this compact little treasury of the wisdom and the wit of the two great masters of statecraft and "unifiers of empire." Be it remembered that in continental parliaments the physician and the surgeon are far more numerously represented than in our own, and that many of the discussions, of which this volume gives us the etherialised essence, were provoked or shaped by the interpellations of medical deputies. A Virchow in the German Chamber, a Tommasi-Crudeli or a Moleschott in the Italian one, cannot fail to imprint their finely-trained intellects on the debates in which they take part, and it is one of the charms of Signor Mariotti's skilful compilation that not only does he make us hear Cavour and Bismarck at their best, but that he enables us to catch the echoes of far-reaching discussions to which the medical interlocutor has contributed the scientific thoroughness and the philosophic calm.

NOVEL MODES OF BURIAL.

THE literature of burial continues to increase as one or other modification of custom commends itself to some as more wholesome or convenient. The latest contribution we have seen is from the pen of Colonel T. Martin, formerly sanitary commissioner in Bombay and Scinde. This writer, while disposed in certain cases to advocate cremation of the dead, prefers for various reasons to maintain the practice of burial, subject to extensive changes in its principle and methods. He does not agree with ourselves in condemning without reserve many of the customs now in use. Far from advising an "earth-to-earth" system and the exclusive use of perishable coffins, he prefers a form of the latter which is air-tight and durable, though fitted with a valve intended to open underground. An elaborate system of subterranean ventilating tubes, with shafts attached which rise high above ground, is contrived to carry off putrid gases; and the design of the whole arrangement is to allow of spontaneous decomposition without direct contact of the body with the earth. The duration of such a process, we must conclude, is practically unlimited. For seaport towns, Colonel Martin has devised a similar method, inasmuch as the coffins are impervious, but with this difference, that burial takes place at sea. His objections to the earth-to-earth system are two. There is, first, he observes, the absorption of decaying matter by the soil and the chance of contamination of neighbouring springs by drainage from that soil; and, secondly, the greater risk from contagion where this exists if bodies are carried in lightly-made cases than if they are placed in close coffins. Now, neither of these objections is really valid. It is a standing rule of burial that cemeteries should never be laid out in the neighbourhood of a water-supply; while, on the other hand, filtration of putrid matter in a porous soil in which oxidative processes are rapidly going on is not to be dreaded as a source of contamination for wells at a distance. The infection, again, which hangs about a body after death may in any case be rendered innocuous while it is carried to its last resting-place by antiseptic materials, and these may even be of such a kind as to assist disintegration, if not putrefaction, after interment. With regard to sea-burial, there is always this objection, common to it and cremation, that the body so treated is not recoverable if required for judicial investigation. Taken altogether, the new system is, in our judgment, inferior, alike from its elaborate complexity and in respect of its sanitary promise, to the old, when that is rationally carried out and the mortal dust is freely surrendered to the earth itself.

THE HOSPITAL SATURDAY FUND.

THE thirteenth street collection in connexion with the Hospital Saturday Fund, of which Mr. Samuel Morley is the President, will take place to-day (the 17th inst.), when some 1800 persons will take charge of collecting-boxes. Of these 400 will be placed in the East and West Central districts, under the immediate control of the central office of the fund, and the remainder of London will be mapped out into twenty-four districts for the purposes of collection, each district having its own local committee. The efforts of the board of delegates—mainly working-men themselves—are chiefly directed to increasing the collections in the workshops of the metropolis; and this source of income, systematically conducted throughout the year, yields the larger result, although trade depression explains a considerable diminution in this branch of revenue.

OVERCROWDING AT BERLIN.

STATISTICS have been compiled which give anything but a favourable picture of life among the poor in Berlin. The capital of the German Empire contains about 40,000 houses, and of course a certain number of these are high-class mansions, where only one, or at most two, families reside. But, according to *Das Echo*, 2500 houses are divided into from sixteen to twenty apartments each; then there are 20,000 houses which have from twenty to thirty tenements each, and 1000 that are subdivided into more than thirty lodgings. Among these apartments or tenements there are 75,000 consisting of only one single room, which are inhabited by 270,000 persons; this gives an average of four inmates for each room. The apartments divided into two rooms also number about 75,000, and these are occupied by 360,000 persons. Finally, there are 30,000 apartments of three rooms, holding 140,000 persons. Such figures only feebly show the promiscuousness in which a large proportion of the Berlin population live, for they only give us averages, and individual cases are infinitely worse than the average. The houses in the poorer quarters are five and six storeys high, and built so close to each other that there is insufficient light and air. Filth and repulsive odours are the natural result. Many rooms are furnished with but one bed, which serves indiscriminately for the father, the mother, the children, and sometimes even for a lodger, who pays some trifle towards the rent. Naturally the education of the children is neglected, and Berlin is renowned for the extra-

ordinary number of juvenile criminals who prowl about its streets. From a sanitary point of view the death-rate of Berlin is one of the highest among the large towns of Europe: it is not difficult to trace the effect to its cause.

DUTIES AND DIFFICULTIES OF POOR-LAW MEDICAL OFFICERS.

OUR attention has been drawn to the report of a meeting of the Steyning Board of Guardians, at which an application was made by Mr. Medcalf for fees for attending two urgent cases (one undoubtedly a pauper case) *without* orders, which led to a long controversy amongst the guardians in reference to payment, ending in their agreeing to pay the fee in respect of the case of the pauper. We may take advantage of this case to make a few suggestions to Poor-law medical officers generally, when placed, as they often are, in similar circumstances. In cases of urgency happening to an undoubted pauper, time not allowing for the procuring of an order from the relieving officer, an overseers' order ought to be obtained; but in very extreme cases, as rupture of bloodvessels, fits, poisonings, drownings, &c., no Poor-law medical officer ought to hesitate to go even without an order. Also in reference to pauper midwifery, it is better for the medical officer to attend urgent cases without order than run the risk of being considered inhumane, as very few boards of guardians would refuse payment under such circumstances. There is no question but that Poor-law medical officers have many difficulties to contend with, from which they are not protected by the Local Government Board or guardians, entailing upon them extra work and anxiety, without adequate, often without any, pecuniary remuneration—a state of things, however, which happens, more or less, to all public men.

TENDON JERK AND MUSCLE JERK.

A PAPER was communicated by Drs. S. Weir Mitchell and Morris J. Lewis to the recent meeting of the Association of American Physicians upon Tendon Jerk and Muscle Jerk in Disease (*Boston Medical and Surgical Journal*, No. 25). They held that the knee phenomenon was a direct muscular response, and not due to reflex action; and showed that every muscular exertion, such as winking, if accurately timed, exaggerates these phenomena. To demonstrate this the patient should lie down with the knee slightly bent. At the time that the tendon is tapped, or just before, the patient is directed to wink, and it will be noticed that the jerk is much increased. This is more beautifully shown in the act of phonation, the patient being directed to count strongly, bringing the whole chest into play at the time the test is applied. A decided sensation, such as heat, cold, or an injury, will increase the responsive power of the muscle or tendon which has been struck. Both the tendon and the muscle jerk are reinforced by irritation of distant parts—a phenomenon which has been attributed to an increase of tone in the muscle. This reinforcement disappears when the muscles are cut off from the spinal centres. Observations upon twenty-three cases of locomotor ataxy were also presented in the paper, the cases being classified according to the degree of swaying movement when the patient is standing with the eyes shut. Four classes are thus distinguished: (1) those in which station was normal, (2) those in which it was slightly impaired, (3) those in which it was greatly impaired, and (4) paralytic cases. In the cases examined, the knee and ankle jerks, and their reinforcement, were absent at the time when the cases came under observation. The changes in the arm jerk seem to advance in the same way as those in the leg jerks, although they came on later. In the paralytic stage the muscle jerk is increased, although the reinforcement is absent. In the first stage of ataxy the tendon jerk is diminished or absent, while the reinforcement is fair; in the subsequent stages both the tendon jerk and its reinforcement are absent. The muscle jerk and its reinforcement continue normal through the first two stages; in the third stage, while the muscle jerk is normal, the reinforcement is absent. In the fourth stage the muscle jerk is increased, in the fifth it is diminished, and in the sixth it is absent as well as the reinforcement. The increase of the muscle jerk late in the disease may be due to some as yet undetermined irritative changes in the muscle. They noted also, in associated movements, that in some cases, if the patient is directed to shut his right hand, the left hand will also shut to a certain extent, and if he is sitting down the leg may be drawn up. This condition becomes more marked, with increase of the ataxy. Another symptom noted was a certain degree of prominence of the eyeballs.

THE SEWERAGE OF RICHMOND.

ANOTHER attempt is about to be made to deal with the vexed question of the sewerage of Richmond, which in common with neighbouring places, is notorious for the multiplicity of schemes which have been advocated, and for the fact, notwithstanding them all, that it still allows sewage to pass into the Thames. A scheme has been contrived which will include Barnes, Mortlake, Kew, and Petersham. Another public inquiry by a Local Government Board inspector must be held with a view to raising the necessary loan of £96,000; and if we may judge by precedent, and by the amount of opposition which is threatened, leading engineers and authorities on the question of sewage disposal will be brought together by the various promoters and opponents, and another long inquiry will result. But whether the work is to be done by the authorities separately or collectively, we trust that steps will before long be taken to remove the sewage from this portion of the Thames.

REMNANT OF PUPILLARY MEMBRANE.

DR. VAN DUYSE, of Liége, has been able to examine microscopically an adult eye presenting a membrane passing in front of the pupil—being, in fact, the remnant of the pupillary membrane of the fœtus. It consisted of a quadrangular film, situated on the anterior surface of the lens, and bound by filaments to the inner circle of the iris. These filaments, under the microscope, appeared to have been capillaries from their endothelial nuclei, and they were composed of fibrillar connective tissue. The central film was composed of connective elements immersed in a transparent substratum; here and there epithelial cells were seen. In the centre of the membrane there was a pyramidal prominence consisting of connective tissue.

FOREIGN MEDICAL APPOINTMENTS.

DR. THEREMIN has been appointed Chief Medical Officer to the St. Petersburg Foundling Hospitals, in place of the late Dr. Frœbelius. Dr. Levashoff, of the Military Medical Academy, has been appointed Professor and Director of the Therapeutic Clinic attached to the University of Kazan. The ordinary Professorship of Psychiatry in the University of Kazan has been conferred on Dr. Bekhtereff. Dr. W. Roux has been appointed Extraordinary Professor of Anatomy in the University of Breslau. Prof. Grashey, of Würzburg, has accepted a "ruf" as Professor of Psychiatry in the University of Munich. We are glad to hear that Professor Bollinger, of Munich, is now sufficiently well to announce the resumption of his lectures. Dr. Carl Gussenbauer, Professor of Surgery, has been elected Rector of the German University of Prague.

INSANITARY STATE OF THE BLACK COUNTRY.

THE oft-proved causal relation between poverty and disease is just now strikingly exemplified in the so-called Black Country stretching between Birmingham and Wolverhampton—the centre of the South Staffordshire iron trade, which has long been in a state of great depression. Dr. Gresswell, an inspector of the Local Government Board, attended last Monday before the Tipton Board of Health to report grave defects in the local sewerage arrangements. There and at Dudley Port he found scores of houses without privy accommodation, the people compelled to rely for their water-supply on wells near ashpits. Scarlet fever and small-pox had prevailed, and the population generally bore traces of physical weakness and impaired health. The chairman of the Board thanked the inspector, and a very evident desire was manifest to do all that was possible to meet the evil; but, to quote the official statement, "Tipton is in a great state of poverty; people do not pay rent; and landlords and landladies, no richer than the tenants, cannot put property in repair, or reimburse the Board if they make the outlay." In the neighbouring town of Wednesbury also there is much poverty, and here a serious epidemic of measles has prevailed for some time, and as yet shows no signs of abatement. The first death from that disease occurred in the week ending April 30th. Towards the latter end of May a marked increase was noticeable, and twenty-nine deaths from measles have occurred in Wednesbury between June 4th and July 9th. By far the largest number of cases arose in the poorer parts of the town, in which likewise the fatality is greatest, chiefly as the result of want of treatment in the early stages. Of the twenty-nine deaths above referred to, no fewer than twelve were complicated with pneumonia, four with capillary bronchitis, and one with convulsions. Dr. Arthur Underhill and Mr. Walter Garman, respectively medical officers of health at Tipton and Wednesbury, are doing the utmost, in conjunction with the local authorities, to remedy the evil. The state of things calls for sympathy more than blame. A revival of the iron trade would soon put matters right; for to crowds of men in times of peace, as to armies in war, nothing is more fatal than want of the necessaries of life and the undermining influence of moral depression.

DEATH IN AN ASYLUM: HOW?

A CASE of sudden death, either accidental or resulting from injuries inflicted by some person or persons other than the deceased, has just occurred at the Surrey County Lunatic Asylum, Wandsworth Common. Dr. Biggs, the medical superintendent, pronounced the evidence of certain lunatics who alleged that they had witnessed an assault by attendants trustworthy so far as their mental condition was concerned. The coroner's jury seem to have doubted this affirmation, and to have given the attendants the full benefit of the doubt. The case is obviously one which calls for a more searching inquiry, and we venture to hope the Home Secretary will order a further investigation. The matter ought not to be left where it is.

LEICESTER AND VACCINATION.

WE have lately shown how the boasted immunity of Leicester from small-pox depends on the revaccination of its official sanitary staff. This does not protect the unvaccinated, who in various ways of life are pretty sure to be caught by the loathsome disease. The number of unprotected, ripening for a harvest of disease, blindness, and death, goes on increasing under the lead of the blind guides of the town. Out of 2500 children born in the last six months, only 300 have been vaccinated. Prosecutions for non-vaccination are suspended, and the people are acting accordingly.

LARGE BILIARY CALCULUS.

AT the recent meeting of the Paris Société de Thérapeutique, Dr. Bouloumié exhibited a biliary calculus weighing 20 grammes = 5·144 drachms. It was of cylindroid shape, and measured 2 inches in length, 3¼ inches in circumference, and on section 2 inches in the long axis of the exposed surface. The calculus consisted almost entirely of cholesterine, with layers of biliary colouring matter, and a small quantity of salts of lime. The patient, a female aged fifty, had had several attacks of hepatic colic, but made a good recovery.

THE HOSPITAL SUNDAY FUND.

THE sum received at the Mansion House up to Thursday evening last reached £35,000. This amount is £5500 in excess of that paid in at the corresponding period last year. Many contributions have yet to come in, which, we trust, will bring up the fund to a total somewhat commensurate with the size and wealth of the largest and richest city in the world.

TUBERCLE OF THYMUS.

A VERY small child, the issue of healthy parents, died from marasmus forty-two days after birth. At the necropsy, three tubercles each the size of a pea, and a fourth one the size of a nut, were discovered in the thymus gland. Microscopical examination detected the presence of the characteristic bacilli, though not in great numbers. There were no tubercles in any other organs. The child had been fed with boiled cow's milk. Demme, who records the case in the *Fortschritte der Medicin*, No. 9, regards it as one of congenital tuberculosis.

SMALL-POX AT MARSEILLES.

Le Journal de Médecine et de Chirurgie for June reports that the epidemic of small-pox which has prevailed in Marseilles during the last nine months continues to increase in severity, and yet the people seem very averse to vaccination. The disease proved fatal to 953 persons in the first three months of this year, but only 325 were vaccinated in the dispensaries specially established for that purpose in different parts of the city. With such a state of things in the principal Mediterranean seaport, and with cholera on the shores of the Adriatic, our countrymen may well be circumspect in going far south for their summer holidays.

CATHETERISM OF THE URETER.

DR. LÉO WARNOTS, surgeon to the Hospital of Saint Jean, has been awarded the degree of Doctor of Medicine with *la plus grande distinction* by the University of Brussels, for his thesis on "Catheterism of the Ureters in the Female." The author discussed the methods of G. Simon and of Pawlik, collecting a large number of facts in support of his views, and thus contributing to show that this operation may in some cases be of great value where operative interference with the kidneys of a female patient are contemplated.

THE PASTEUR INOCULATIONS.

IN Vienna Dr. Ullmann, assistant to Prof. Albert, has inoculated thirteen persons who had been bitten by animals thought to be rabid. Dr. Barattieri is establishing a Pasteur Institute in Milan. Both Dr. Ullmann and Dr. Barattieri have studied the subject in Paris with M. Pasteur himself.

DR. SEMMOLA, Professor of Therapeutics in the University of Naples, has been raised by Royal Warrant to the dignity of a Senator of the Kingdom of Italy.

THE Madrid Jennerian Society, which has for some years past been the centre for discussions on questions connected with vaccination arising in the Spanish capital, has ceased to exist—at least as a separate society,—various causes having combined to render its fusion into a more comprehensive scientific body desirable. The Medico-Chirurgical Academy has, after some time spent in negotiations, consented to absorb it, and to constitute a Vaccinological Section. The presidency of the new section has just been conferred, after election, on Señor Serret, editor of *El Genio Medico-Quirurgico.*

THE Administrative Committee of the Cantonal Hospital of Geneva has introduced an innovation in the mode of election of members to its medical staff. The committee determined that a competitive examination should decide which of the candidates were to be appointed. Under this new system M. Goetz was appointed physician, and M. Comte surgeon to the hospital; M. Cordes to be surgeon to the maternity.

MUCH sickness having prevailed amongst the troops occupying the new barracks at Gosport, owing, it is believed, to the foul condition of the old moats hard by, the War Office has ordered the barracks to be closed for two months, the men being directed to remove to the forts outside the town.

SIR W. MAC CORMAC'S "Notes of an Ambulance Surgeon" have recently been translated into Japanese, and the original illustrations have all been faithfully and cleverly reproduced both in the form of lithography and woodcuts. The name of the translator is Brigade-Surgeon Yakoi, of the Imperial Army Hospital, Yeddo.

M. PONCET stated at a recent meeting of the Paris Biological Society that he had always found microbes in chalazæ, which could be cultivated, the culture applied to the conjunctiva of a rabbit setting up a violent inflammation and quickly producing hypopion.

REPORT
OF THE
Lancet Commission
ON THE
POLLUTION OF THE THAMES AT THE HENLEY REGATTA.

THE growing popularity of regattas on the Upper Thames is giving rise to a new sanitary danger which must not be overlooked. Local authorities have not yet fully realised that when an exceptional number of persons congregate together special precautions must be taken. We are always ready to denounce the pilgrimages practised by Eastern populations; but at home our boat-races and our horse-races are so many small Meccas, that endanger alike the health of the visitors and the surrounding inhabitants. By fasting and fatigue the Mahomedan pilgrim increases the risks of his journey. By feasting and over-exertion the English pleasure-seekers and athletes also favour the outbreak of disease. It will be urged that in England the crowd, though immense, is so quickly gathered together, and then so promptly dispersed, that there is no time for any serious evil to arise. Also, if the towns or villages near a great racecourse are overcrowded for a day or two, these localities may profess to be properly administered by competent sanitary authorities and drained in the best way possible. There is, nevertheless, many reasons to doubt the efficiency of sanitary arrangements in towns renowned for their sporting associations. In any case, if the houses on land are under some sort of control, it is only too evident that the increasing number of habitations which float about on the water altogether escape any such supervision.

Formerly a regatta brought a few thousand people to the river-side for the brief space of an afternoon, and naturally no serious consequences were anticipated. But now the Henley Regatta is no longer limited to an afternoon, but it is prolonged for three whole days. People do not merely crowd on the river-bank for a few hours, they come and live on the water for the better part of a week. Not content with filling every house on shore with lodgers and visitors, houses are now built on old barges, and these, tugged up the river, anchored close to each other, have converted the pure stream into a dirty street. One or two house-boats might be allowed, but last week along the length of the course, for a distance of about a mile, these houses, closely packed, were stationed for several days. Here and there we have a steam launch, a large boat, or some other sort of craft; but these vessels, whatever their shape or name, are inhabited, and therefore contribute to the pollution of the river. Most of the house-boats and many of the other craft have closets on board, which drain directly into the water. The law forbids direct drainage into the Thames, but these house-boats openly disregard this law. The various towns and villages situated beyond the intake of Thames water for the drinking-supply of London are put to the greatest trouble and expense in order to dispose of their sewage without polluting the river. The many schemes for dealing with the drainage of the Thames valley, so as to prevent the contamination of the river on which London depends for its supply of potable water, have been discussed over and over again in these columns. Yet while so much trouble is taken, so many financial sacrifices imposed, to settle this difficult and complicated question, an increasing number of mere pleasure-seekers are allowed to set these sanitary precautions at defiance, just at the season of the year when their strict observance is most necessary.

The origin and development of the cholera germ are not yet known. It would be impossible to say what amount of germs is necessary to pollute a river, or how far these organisms would travel down a stream without losing their vitality. But that cholera follows the watercourses was fully demonstrated by the recent epidemic in Spain. Now the cholera has broken out again in Italy, and, of all places, in one which most affects the interests of England. At Brindisi, where travellers to India by the overland route embark and disembark, the cholera is now prevailing. Further, it is evident that a large proportion of persons coming from India belong precisely to the very class most likely to attend festivities such as the Henley Regatta. These persons, by stopping a few hours or days at Brindisi, might bring over with them the germs of cholera—just as, last year, sailors from Barcelona and other ports of Spain brought cholera over to English towns. At Bristol, notably, where a sailor died of Spanish cholera, it was possible to disinfect the drains of his house and prevent the disease travelling further. But if, at the Henley Regatta, anyone living on a house-boat had been seized with cholera, the specific germs would, in all probability, have been discharged into the Thames. What mischief would have ensued we are unable to surmise. It is to be hoped that the dejections of more than one cholera patient are necessary to contaminate a river; but we have no certainty of this immunity. Also, if the germs did not travel down as far as the water intake at Teddington, it must not be forgotten that the water of the Thames is employed on the spot. If most persons have the prudence to avoid drinking this water, their servants do not scruple to use it for washing plates, &c. Hence the presence of cholera on one house-boat might well communicate the disease to other similar crafts floating close by, but lower down the river.

On land at Henley it will be found that the inhabitants drain into cesspools. They suffer, therefore, from all the inconveniences of this system. The wells, as usual, are placed too near to the cesspools, and are consequently often contaminated. Sore-throat, scarlet fever, and diphtheria, are too well known at Henley. Yet these risks, this danger and suffering, are endured because the inhabitants of Henley feel that it is their duty not to drain into the Thames. If a humble cottager living on the banks of the river sought to protect the lives of his children by removing his

cesspool and substituting a small pipe to drain direct into the Thames, he would be prosecuted. But numerous and fashionable people, who in the superfluity of their wealth can purchase or build house-boats, are allowed to have closets on board that empty into the water which we in London are compelled to drink.

This is not the only grievance. The services of dustmen and scavengers are alike judged superfluous. All the refuse—the offal, garbage, and rubbish resulting from so many picnics and so much feasting—is thrown overboard. The appearance of the river was simply scandalous. Out in the middle of the stream we saw floating slowly away every sort of refuse; a portion of course got entangled between the shore and the boats and there formed unpleasant accumulations. Opposite the "red cottages" on Saturday, the day following the last race, we visited a house-boat and examined the nature of the waste materials floating between this dwelling and the shore. There was a great number of decomposing salad leaves, some rotten fruit, innumerable egg-shells with part of the yellow of the eggs still adhering, several large pieces of bread, the skin of a salmon, a skirt of lamb, stale pieces of fat and meat, some spring onions, innumerable crushed lemons, faded flowers, lobster-shells, bruised tomatoes, and a dead roach. A bucketful of water taken from the midst of this garbage smelt very unpleasant. On applying Nessler's test it gave a deep reaction, pointing to the presence of organic contamination. A few yards lower down the river we met with another dead fish. Perhaps the pollution had proved fatal to these fish. The various creeks down the river, where the action of the current is feeble, were very foul indeed, and we heard many complaints concerning the abominable odours that arise in such places.

Close to the starting-point of the race-course there is a small creek where the water seemed exceptionally foul. Special complaints had been made of the bad odours arising at this particular spot. The water had a curious musty vegetable smell. Without attempting any quantitative analysis, by merely applying Nessler's test the colouration obtained was so intense that it was evident the amount of ammonia must have exceeded a grain per gallon. Indeed, by boiling some of the water with caustic potash, the smell of liberated ammonia was quite distinct. Thus, where the water is comparatively stagnant the amount of organic decomposition noted is enough to account for the most dangerous condition of the surrounding atmosphere; while, even in the open stream, the presence of ammonia can be clearly traced in the water collected round about the house-boats and amidst the garbage which is thrown from these vessels into the river.

That dangers must spring from such a state of affairs is obvious to all, and it is not necessary to point out any individual instance of harm done. But such cases have come under our notice. We have seen and questioned local and other practitioners who have attended cases of malignant sore-throat following closely on exposure to the effluvium which has disturbed garden parties held on the river-bank at the time of the Regatta. It has further been maintained, in our presence, that sore-throats and diarrhœa have affected the rowers who have been exposed to the corruption surrounding the house-boats. At the same time the population on the river is exceptionally healthy. Invalids and delicate persons do not usually participate in regattas, and plenty of out-door exercise will enable the human frame to resist many injurious influences. But this comparative immunity does not justify the contamination of the river.

The Thames, however, might easily be saved from pollution by a few very simple measures. It would, firstly, be necessary to enact a law or bye-law abolishing all closets on board house-boats and other inhabited vessels. It should be the practice to land for sanitary purposes. Secondly, it is absolutely indispensable that the sanitary authorities, on both banks, should come to a mutual agreement for the flitting out of a scavenger boat. This boat would come in the morning and take away from all the floating habitations the dust, the night stools, the refuse and garbage collected during the previous twenty-four hours. When this facility has been provided, then anyone throwing rubbish into the Thames should be prosecuted. A few detectives could watch, and, by making an example of the first cases, the practice would soon be stopped. Neither of these measures would entail any great outlay, and even those most concerned would willingly submit to regulations obviously made in their own interest as well as in the interests of the community at large.

THRUST WOUNDS THROUGH THE ORBIT.

THE roof, and more especially the inner wall of the orbit, is so thin and fragile that a comparatively slight thrust with a pointed or a blunt instrument, like the end of an umbrella or of a walking-stick, may be sufficient to penetrate into the closely contiguous brain substance. Such a case was placed on record in THE LANCET of June 19th by Dr. Campbell Pope and Mr. Rickman Godlee. Aphasia ensued, but under judicious management the patient made an excellent recovery; and the opportunity is a favourable one for reviewing a class of comparatively rare injuries possessing exceptional anatomical and clinical interest.

We have the authority of Sir Prescott Hewett and Mr. Whitaker Hulke for the statement that "in no class of cases is the surgeon more likely to be put off his guard as to the exact nature and extent of the injury. At first, all that may be apparent is the slight injury of the external parts—a trifling wound of the upper lid, and sometimes not even that, for the instrument may have slipped under the lid and left merely a patch of ecchymosis on the conjunctiva. Brain symptoms there may be none. Two or three days may pass over, during which the patient goes about as usual; then brain symptoms make their appearance, sometimes suddenly, and the patient dies in the course of a few hours or days, and the true nature of the case is revealed only by the post-mortem examination."[1] Exactly concordant is the most recent authority, Mr. George Lawson, in Christopher Heath's "Dictionary of Practical Surgery": "One curious fact connected with these punctured fractures of the orbit is that the severe nature of the injury is often overlooked; the external wound may be small, the immediate symptoms may be trifling, and the exact injury is not even surmised." The patient may be able to continue work for some time, then become delirious, comatose, and die, or recover under the most extraordinary circumstances. In THE LANCET, 1837-8, vol. ii., p. 16, Mr. Congreve Selwyn, consulting physician to the Ledbury Dispensary, recorded the case of W. B——, aged four, who fell on the floor whilst eating his dinner. The knife—a common cheese-knife, about 4½ in. long in the blade, and averaging three-quarters of an inch broad—entered the right orbit nearly horizontally to the depth of three inches and a quarter, immediately beneath the superciliary ridge, and penetrating (through the posterior part of the orbital plate of the frontal bone) the substance of the brain, injuring in its course the optic nerve. It required all the father's force to dislodge the knife from its situation. Hæmorrhage was very slight. Some portion of the brain protruded after removal of the knife, and more was discharged on the eighth day after the injury. Some sleeplessness and delirium followed, but under low diet, little or no medical treatment, and the application of strips of adhesive plaster to the wound, healing was complete in six weeks, and the patient was alive and well seventeen years after.

In illustration of the little importance sometimes attached to these orbital thrust wounds at the time of infliction and of their terrible import, no more striking case can be adduced than one here abridged from a letter of Sir Philip Crampton: "In the winter of 1814, a lieutenant in a Highland regiment, when running on a dark night to escape from a shower of rain, came rather violently in contact with an irritable old man, who made a thrust at him with an umbrella, the point of which struck him immediately beneath the left eyebrow. The wound was attended with so little local pain or shock to the system, that the patient walked to my house in Dawson-street (a distance of at least half a mile), and having mentioned the occurrence as one to which, however, he attached no importance, he begged of me to look at the wound in the eyelid, which still continued to bleed slightly. I found a wound of about three-fourths of an inch in length in the upper eyelid, exactly in the seat of the deep fold which is formed in this part by the action of opening the eye and looking upwards. When the eyeball was turned up, there was no appearance of wound, but when the eyelid was drawn downwards the wound gaped, and showed the conjunctiva, which still completely covered the upper portion of the ball of the eye. The vision was quite unimpaired. The wound having been united by two points of

[1] See Holmes' System of Surgery, third edition, vol. i., p. 585-6.

suture, the patient walked to his lodgings in Grafton-street. I called on him the next morning, and found him at breakfast; he made no complaint but of some stiffness in the eyelid. The following morning, at 7 A.M., I was called to him in a hurry, and found him in very strong convulsions, which continued with short intervals of coma until 8 or 9 o'clock in the evening, when he expired. At the post-mortem examination the brass ferrule of the umbrella, nearly two inches in length, was found to have penetrated through the orbital plate of the frontal bone, and was lodged in the substance of the left hemisphere of the brain; it was embedded in a thin coagulum of blood, which extended into the left lateral ventricle."[2]

An equally formidable injury, though happily unattended with loss of life, was published in THE LANCET for 1862 (vol. i., p. 626) by Mr. W. R. Beaumont, formerly professor of surgery in the University of Toronto. A man while looking on at a rocket being fired felt a terrific blow on the left eye. He walked some thirty yards to a tavern, where he was seen in about ten minutes by Mr. Beaumont. He was sitting in a chair, with pale face and lips and extremely small weak pulse. No expression of pain; no symptom of cerebral lesion. Vision of the eye on the injured side was immediately and completely lost, but the eye itself appeared uninjured. The only mark of injury visible was a thin splinter of wood, not half an inch long, projecting from the orbit immediately above the inner canthus. Mr. Beaumont adds: "I placed the man on the floor, half recumbent, his head and shoulders being supported. I then endeavoured to extract with tolerably strong forceps what I supposed to be a small portion of a rocket shaft, but I found that I could not stir it. I sent for and soon obtained a pair of strong, flat-bladed pliers, with which even I could not move by direct traction the extruded shaft, so tightly was it wedged between the bones through which it had passed. Knowing that the shaft of a rocket is not round like that of an arrow, but square, I was aware of the small extent to which it could be rotated on its axis; still I found on trying to do so that a slight degree of movement on its axis was not impossible, and by turning it several times a few degrees alternately to the right and to the left I at last loosened it, and slowly drew out five inches and a half of the rocket shaft, the transverse section of which proved to be four-tenths of an inch square." A profuse gush of blood followed, but ceased in a few minutes after the application of iced water. The patient did not even faint, and in less than fifteen minutes, without any help, got up from the floor and walked. He suffered severe headache and vomiting during the first twenty-four hours, but not much pain after that. In three days he was dressed and walking about his room. The wound healed very readily, with scarcely any suppuration; no piece of bone came away. There was no paralysis except loss of vision of the left eye and loss of sensation in parts of the infra-orbital nerve. The only treatment adopted was cold water to the head and a few doses of calomel and jalap. Forty days after the accident the man was in good health and perfectly well, excepting left blindness. He continued so when again seen after a lapse of three years, but he complained of his memory being decidedly impaired. As to the exact course which the rocket shaft had taken, Mr. Beaumont adds, "It seemed, as I withdrew it, to have passed almost directly backwards, nearly parallel with the mesian line, apparently through the sphenoidal fissure, and into the base of the middle and posterior lobes of the left hemisphere of the brain; but as it had not killed him, nor even caused any symptoms of cerebral lesion, one can scarcely think that it had taken this direction, especially as all the nerves passing through this aperture had escaped uninjured. . . . . I am sure from the direction of the shaft, as I slowly extracted it, that it had not passed obliquely downwards into the pharynx, and therefore that it must have taken a course either immediately above or below the base of the skull. Under either condition the patient's escape from death renders the case one of the most remarkable in the annals of surgery."

For notes of the following hitherto unpublished case we are indebted to Mr. A. F. Hawkins, obstetric surgeon to the Queen's Hospital, Birmingham. A female pupil (aged three) at a neighbouring Board school fell on the floor while in the act of knitting, and broke one of the needles. Two pieces were found, measuring respectively three-quarters of an inch and four inches and three-quarters, but on joining them and comparing them with the other needle it was evident that a considerable piece was missing. The child seemed dazed for a moment, but then went on with her lessons, the schoolmistress noticing at the time a spot of blood above the eyelid and just under the eyebrow on the right side. The next day the child again attended school, apparently all right, but when she presented herself the following day she did not seem quite so well, and it was deemed prudent to take her to the Queen's Hospital Casualty Department, at the time in charge of Mr. Hawkins. He noticed a small scab where the blood-drop had appeared at the time of the fall, but as the child presented no special symptoms, he advised that she should be taken home and carefully watched, diligent search to be again made for the missing piece of needle, and the child to be brought to the hospital at once if in any way complaining. Next day (fourth from the accident) the child was brought to the hospital with paralysis of the left side, more marked in the upper than in the lower extremity. Mr. Hawkins at once summoned a consultation, which was attended by Mr. Bennett May and Mr. Priestley Smith. The child was placed under chloroform, and an incision made through the eyelid and subjacent tissues in the situation of the original blood-spot. At a depth of about three-quarters of an inch the probe came in contact with a hard substance, which was seized with a fine pair of forceps and drawn out, proving to be the missing piece of knitting-needle, of which the annexed woodcut is an exact representation. As the child was lying flat on the table during the operation, it was specially noted that in drawing out the needle it was almost perpendicular to the eye; if the deeper end deviated at all, it was slightly upwards. The symptoms of paralysis continued for ten days, when they began to subside. They then did so rapidly, and the child was well within another week. She continued so when seen a year afterwards.

The concurrent practical teaching of these cases is that great importance must be attached to all wounds, however small and apparently insignificant, in the neighbourhood of the eye as well as in the globe itself, especially if there be the slightest reason to suspect penetration and lodgment of a foreign body. In consequence of the looseness of the soft tissues, and of the bony spaces in the neighbourhood of the eye, it is not difficult to understand that foreign bodies may be driven into, and ensconced in, comparatively safe quarters, though apparently driven into the brain. But in some cases the symptoms, in others the necropsy, place beyond doubt brain penetration in some thrust wounds through the orbit. Immediate extraction is obviously indicated when any portion of the offending agent can be seen or felt, and the last-mentioned case in the series justifies the prudence of cutting down to search for the foreign body, when its presence is strongly indicated by the facts and history of the accident, and by the evolution of nervous phenomena.

GEOGRAPHICAL DISTRIBUTION OF FATAL CANCER DISEASE.

THE recently issued annual report of the Registrar-General for the year 1884 contains some valuable statistics bearing upon the marked increase of the recorded death-rate from cancer during the past thirty-five years, and upon the geographical distribution of this disease. The increase of the mortality from cancer in England and Wales in the ten years 1871-80, compared with the ten years 1851-60, was equal to 62 per cent. among males, and to 43 per cent. among females. It also appears that the increase between these periods, both among males and females, was greater at each successive age period after thirty-five years. The report points out that "the very unequal increase in the male and female cancer mortality seems difficult of explanation on the hypothesis that the general increase has been altogether real, and not in great part only apparent." It is suggested that

the more probable explanation of this inequality is the fact that "the cancerous affections of males are in a much larger proportion internal or inaccessible than are those of females, and consequently are more difficult of recognition, so that any improvement in medical diagnosis would add more to the male than to the female figures." This argument gives reasonable probability to the supposition that a very considerable, though unknown, proportion of the increase of recorded cancer mortality is really the result of improved diagnosis. With regard to the geographical distribution of fatal cancer, the report gives a table showing the mean annual death-rate from this disease in each of the registration counties in England per 1,000,000 persons, male and female, living during the ten years 1871-80; these rates have been laboriously corrected for variations of age and sex distribution in the county populations, and are therefore strictly comparable. The most noticeable feature of this table is the marked excess of cancer mortality in London; this apparent excess would, however, certainly be lessened, and might disappear, if it were possible to eliminate all those fatal cases imported into London for hospital treatment or operation. A somewhat similar explanation is suggested for the excessive mortality in Devonshire, on the ground that the coast of that county includes so many health-resorts of sick persons. It is pointed out, however, that the corrected cancer death-rates in many of the counties around London also show a considerable excess, indicating that this part of England, especially the Thames valley, is favourable to the development of cancer. It has long and generally been asserted that cancer is specially prevalent in fen districts and in low-lying ground, and the accuracy of this widely accepted opinion is corroborated by these new statistics. The counties of Cambridge, Northampton, Huntingdon, and Bedford all show cancer death-rates considerably above the average; at the same time, however, it appears that in Essex and in Lincolnshire the rate from this disease was below the general English average. It is pointed out that in most of the mining and industrial counties, the cancer death-rate is below the mean rate in agricultural counties; and, further, that almost all the highest county rates occur in the eastern, and most of the lowest in the western, half of the kingdom. There are, however, enough exceptions to these generalisations to forbid their unreserved acceptation. Judged, however, by the recorded facts of the thirty years 1851-80, the highest mortality from this disease is shown in London and the three registration divisions adjoining London; while the divisions with the lowest mortality are the north-western, the north-midland, and the Welsh. In dealing with the figures, and drawing conclusions therefrom as to the geographical distribution of fatal cancer, it should constantly be borne in mind that the value of the recorded facts depends entirely upon the accuracy of the medical diagnosis and certification of the cause of death, as entered in the death register. It may safely be assumed that there is an intimate relation between general accuracy of diagnosis and the proportion of duly certified deaths. In connexion with this, it may be pointed out that the recent proportion of uncertified deaths was only 1·3 per cent. in London, whereas it ranged upwards in the other divisions to 8·5 in the Welsh division. It is possible, therefore, that the recorded excess of cancer mortality in London may be partly due to more accurate diagnosis and certification, and the low mortality in Wales to more or less defective diagnosis and certification.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Diphtheria in certain districts in Hertfordshire, by Mr. SWEETING.—This is the last of a series of reports which Mr. Sweeting prepared for the Local Government Board, and it involved investigation into the circumstances of the prevalence of diphtheria in the Hitchin, Bishop's Stortford, and Hemel-Hempstead rural districts, and in the Watford urban district. In the *Hitchin Rural District* the diphtheria mainly affected the village of Whitwell, with its 750 inhabitants. In the epidemic under notice some 53 undoubted attacks of diphtheria came under observation, of which 19 were fatal. The disease was first recognised in August, 1884, but some minor throat ailments had existed before that date, and some fatal attacks of so-called croup had previously occurred in the neighbourhood. But, whatever its origin, the disease lingered in Whitwell up to the end of 1885, when persons were still suffering from the complaint. Milk was excluded as a cause, whereas personal communication between sick and healthy must be regarded as having largely contributed to its spread. Beyond school closure and a little fumigation no action was taken on the part of the authorities to check its prevalence, and no attempt was made by the hire of a cottage or otherwise to provide any means for the isolation of the sick. In the *Bishop's Stortford Rural District* recent diphtheria has been confined to the villages of Braughing and Little Hallingbury. During a first outbreak at Braughing, beginning in December, 1883, eight died; the second outbreak, terminating in August last, only led to one fatal attack. At Little Hallingbury, with a population of 500, there were between June and November, 1885, 63 attacks, of which 11 terminated fatally, the largest prevalence being during August and again in the last week of October. Between the ages of three and thirteen years the percentage of mortality was 2·50; between thirteen and twenty years it was 7·7. The origin of the disease was obscure, for throat affections allied to diphtheria were at the time prevalent in adjoining parishes, and the sanitary circumstances of the first house invaded were bad. The spread of the infection could, however, be easily traced to personal communication; slight cases of non-membranous sore-throat being apparently, in several cases, the links in the chain of diphtheria infection from person to person. But the question of the spread of the infection through the agency of water is also discussed, Dr. Turner, the medical officer of health, having drawn Mr. Sweeting's attention to a curious sequence of cases along the side of a stream which, on the one hand, received sewage from an infected house above, and, on the other, was resorted to for water a little lower down by those who were subsequently attacked. The facts of the case are stated, but it is admitted that they are by no means conclusive. In the *Hemel-Hempstead Rural District*, 13 deaths from throat malady occurred in 1885, school influence largely aiding in its spread, and this especially at Apsley End. In view of this, the health officer advised the closing of the school there, but the advice was not acted on. The actual power of closing a school, subject to an appeal to the Education Department, rests with the sanitary authority, and they can, if they choose, and as they did in this case, disregard the advice of their health officer. In the *Watford Urban District*, diphtheria, which for many previous years had been comparatively absent, caused 28 deaths in 1885; but adding to these the fatal attacks from diseases like "croup," the total fatality amounted to 36. Here, again, there was much obscurity as to the origin of the disease, and locally the question of sewer ventilation was largely identified with the malady. But though the sewers are imperfectly ventilated, there seemed to be an absence of any special link between this condition and the incidence of the disease. No well-considered scheme of school closure was arranged, and the means of isolation available were not such as to secure the stay of the disease by that means. The most remarkable feature about this group of outbreaks is the fact that the disease was widely prevalent over a considerable area of Hertfordshire, and this quite irrespective of the influence of any local conditions that could be recognised. The question of an aerial diffusion and the operation of an atmospheric influence receive support from outbreaks of this character, and this especially when an exhaustive inquiry fails to ascertain the existence of any other cause.

On the Sanitary Condition of the Hollingbourn District, by Dr. PARSONS.—This rural district resembles many others in the country with respect to its imperfect drain and cesspool sewerage, to its common privy and resulting nuisance, and, in part, to its water-supply from wells, which are so situated as to be liable to excremental pollution. The medical officer of health is reported as keeping no journal or notes of his inspection or correspondence, and as making only one general and certain special inspections of his district annually. The information he receives from the registrars is useless, except for mere statistical purposes, and no lists of pauper sickness are supplied to him. In one of the inspector of nuisance's books as many as six or eight months go by without an entry, the duties of the inspectors being,

however, fairly discharged if account be taken of the multifarious duties which detain them in other directions. Into this district scarlet fever was imported, and it prevailed from November, 1885, to April, 1886. The first case came under notice on Nov. 4th, and one official in Poor-law matters tells another official belonging to the sanitary authority about it, and proposes that food &c. should be supplied. Then the district medical officer is told not to enter the attacks in his medical relief list, but to continue attending them on behalf of the sanitary authority. The disease continuing to spread, a nurse was obtained, and the clerk and inspector of nuisances were to supply all necessaries. No report was prepared by the medical officer of health until Jan. 14th, and then he stated that the cottages affected were quite unfit for human habitation, the well unfit for use, and the ground full of cesspools. No attempt was made to isolate the sick. The story as told seems to be one of faulty administration. It is much to be regretted that conditions of house accommodation, &c., are allowed to remain unreported on until the very condition—namely, disease prevalence—which efficient sanitary administration is intended to prevent has actually been brought about. And then, although this rural sanitary authority seem, in their generosity, to have gone beyond their functions in supplying things which were out of their province, yet they appear to have forgotten that their special duty is to prevent disease. From this point of view, whether the action of one or other of the parties concerned is looked at, the steps taken can, as the report says, "only be regarded as a costly failure." Tents, it appears, are kept at the workhouse "for the isolation of small-pox cases." But when scarlet-fever prevails, a disease which kills a far larger number of human beings than small-pox does, and against which no special means of prevention are available, then the tents seem to be kept locked up. What is really wanted in these rural districts is a small amount of isolation accommodation of a permanent character, and this, it must above all things be remembered, should always be available for use at a moment's notice. Then if each officer, whether Poor-law or sanitary, knows what are his special duties, but little difficulty should arise in checking such a prevalence at the onset.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5733 births and 3213 deaths were registered during the week ending July 10th. The annual death-rate in these towns, which had been equal to 16·8, 17·0, and 17·6 per 1000 in the preceding three weeks, further rose last week to 18·4. During the thirteen weeks of last quarter the death-rate in these towns averaged only 18·6 per 1000, and was 2·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 11·7 in Wolverhampton, 11·8 in Huddersfield, 12·6 in Brighton, and 13·1 in Sunderland. The rates in the other towns ranged upwards to 22·3 in Cardiff, 23·7 in Blackburn, and 25·2 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding four weeks from 263 to 333, further increased (under the influence of the recent intense heat upon infantile diarrhœa) to 477; they included 225 from diarrhœa, 116 from measles, 58 from whooping-cough, 33 from scarlet fever, 27 from "fever" (principally enteric), 18 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Huddersfield or in Halifax, whereas they again caused the highest death-rates in Bolton, Portsmouth, and Preston. The mortality from diarrhœa showed a further considerable increase upon the low rates recorded in recent weeks, and showed the largest excess in Salford, London, and Wolverhampton. Measles caused the highest death-rates in Portsmouth, Bolton, and Preston; and "fever" in Portsmouth, and Cardiff. The deaths from diphtheria in the twenty-eight towns included 14 in London. Small-pox caused no death either in London and its outer ring or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had declined in the preceding three weeks from 31 to 14, were 12 on Saturday last; 3 cases were admitted to these hospitals during the week, against 4 and 2 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 184, 194, and 197 in the preceding three weeks, declined again last week to 190, and were 17 below the corrected average. The causes of 81, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Bristol, Brighton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·2 and 20·8 per 1000 in the preceding two weeks, declined to 19·7 in the week ending July 10th; this rate exceeded, however, by 1·3 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·7 and 16·7 in Dundee and Greenock, to 28·6 in Paisley and 29·5 in Perth. The 471 deaths in the eight towns showed a decline of 43 from the number in the previous week, and included 24 which were referred to diarrhœa, 17 to whooping-cough, 11 to measles, 7 to scarlet fever, 2 to "fever," (typhus, enteric, or simple), 2 to diphtheria, and 1 to small-pox; in all, 64 deaths resulted from these principal zymotic diseases, against 65 and 59 in the preceding two weeks. These 64 deaths were equal to an annual rate of 2·6 per 1000, which was 0·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 21 and 10 in the previous two weeks, rose again last week to 17, of which 14 occurred in Glasgow and 2 in Edinburgh. The deaths from measles, on the other hand, which had been 20 and 15 in the previous two weeks, further fell last week to 11, and included 8 in Edinburgh. The 7 fatal cases of scarlet fever showed a decline of 3 from the number in the previous week, and included 4 in Glasgow and 3 in Edinburgh. The 2 deaths from diphtheria were returned in Edinburgh, and the 2 from "fever" in Glasgow; both numbers were considerably below the average. The death classed to small-pox was certified as chicken-pox, and occurred in Edinburgh. The deaths attributed to diarrhœal diseases, which had increased in the previous four weeks from 7 to 16, further rose last week to 24, of which 7 were returned in Glasgow, 7 in Dundee, and 5 in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 93, 86, and 77 in the preceding three weeks, further declined last week to 74, but were 13 above the number in the corresponding week of last year. The causes of 61, or nearly 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·7 and 22·9 per 1000 in the preceding two weeks, rose again to 23·1 in the week ending July 10th. During the thirteen weeks of last quarter the death-rate in the city averaged 25·6; whereas the mean rate during the same period did not exceed 17·2 in London and 19·7 in Edinburgh. The 156 deaths in Dublin last week showed an increase of one upon the number in the previous week, and included 14 which were referred to the principal zymotic diseases, against numbers increasing from 5 to 12 in the preceding four weeks; 4 resulted from scarlet fever, 4 from diarrhœa, 3 from "fever" (typhus, enteric, or simple), 2 from whooping-cough, 1 from measles, and not one either from small-pox or diphtheria. These 14 deaths were equal to an annual rate of 2·1 per 1000, the rates from the same diseases being 3·6 in London and 4·1 in Edinburgh. The fatal cases of scarlet fever and of diarrhœa exceeded the numbers returned in any recent week, while those of "fever" and of whooping-cough were fewer than those in the previous week. Eight inquest cases and 9 deaths from violence were registered; and 59, or more than a third, of the deaths were recorded in public institutions. The deaths of infants and of elderly persons showed a considerable decline from the numbers in the previous week. The causes of 12, or 8 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

THE APPROPRIATION OF PATIENTS BY CONSULTANTS.

To the Editor of THE LANCET.

SIR,—I read with interest in your issue of July 10th the letter of my friend Mr. Henry Kesteven and your remarks upon the subject of "Consultants *v.* General Practitioners." Isolated examples of the injustice of which Mr. Kesteven complains are unfortunately so common that there are few general practitioners who will not be able from bitter experience fully to endorse all he has said. The evil is an undoubted one; the causes and the remedy are not so clear. Both Mr. Kesteven's letter and your leading article contain, I think, indications of, at any rate, one of the causes of the present state of tension. In former years the class of "consultants" was largely recruited from the successful general practitioners. Having passed through the valley of tribulation himself, the consultant of those days was more in sympathy with the general practitioners; he appreciated their difficulties, and was better able to apply practically the ancient rule which bids us do to others as we would they should do to us. Of this class there are happily still many bright examples left us, but I fear they are fast disappearing, and a new and improved (?) order of men are taking their place. The consultant of the present day belongs as a rule, and especially in London, to a separate caste; his very existence depends upon his holding hospital appointments, and his whole professional training is directed towards obtaining the qualifications necessary to comply with the regulations under which such appointments are held. As a consequence, comparatively few modern consultants have passed through the salutary ordeal of general practice, and that fine feeling of sympathy is to a great extent blunted, or even lost, and that through no fault of the individual, but of the system.

An improvement in the relations at present existing between consultants and general practitioners would, I am sure, soon be observable, were some means found to induce the most able and most successful general practitioners to join the upper ranks of the profession as consultants. For the last few years the tendency has been to exclude them. Hospital and other appointments—the essentials of a modern consultant—are awarded not only for merit and professional skill, but also because the aspirant can place after his name certain cabalistic signs unobtainable by the general practitioner as such. We are now beginning to feel the result of such exclusiveness, and are suffering as a profession as much from the "war of class against class" as the political world.

I am, Sir, yours truly,

J. FREDK. W. SILK.

Victoria House, Highgate Hill, N., July, 1886.

To the Editor of THE LANCET.

SIR,—In your issue of July 10th I read a letter from Mr. Kesteven, and a leader by yourself, on that ever-recurring question—the relationship of the specialist to the generalist. One cannot but sympathise with Mr. Kesteven on his having been the victim of ingratitude at the hands of those to whom he referred his patients; but perhaps he has not allowed quite enough for the operation of that force to which he calls attention—namely, the mendacity of the medium between the practitioner and the consultant—viz., the patient. A plausible explanation would occupy too much of a busy physician's time to verify or disprove, and so, in the push and hustle of work, a patient is examined and the fee pocketed without much thought being given to the original source of the income—to wit, the family practitioner. To one who draws his livelihood from a circumscribed neighbourhood the loss of even one patient is no doubt a consideration, but scarcely a serious consideration; for how many patients does one lose in this way? From a sufficiently large experience of general practice, I think I may say not many. The key of the situation lies, not in the conduct of the consultant, but in the confidence of the public, and it is only by the general practitioner gaining in an ever-increasing degree this confidence that he can hope to compete successfully with the consultant. Relieved of responsibility in critical situations, the family practitioner has in some instances become inefficient to meet the crisis, from a long habit of thinking that in such and such a case Mr. A. or Dr. B. can be sent for; others, anxious and quite possibly able to act efficiently, the tradition of his class being unable to cope with difficult cases, withhold that public confidence which confers at once responsibility and status, and conduces to efficiency on the part of the practitioner. In the words of our immortal poet, "It is not in our stars, but in ourselves, that we are underlings," and the remedy of the situation appears to me to lie in the generalist evincing by word and deed his absolute equality with any other section of the profession, rather than by his desiring a perpetual protection from the consultant.

I am, Sir, yours obediently,

Green Lanes, N., July, 1886. ALEXANDER MORISON, M.D.

SPINA BIFIDA CASES.

To the Editor of THE LANCET.

SIR,—Since my last communication to you on this subject, I have operated upon other two cases, one of these on June 10th, which is now contracted and safe, the other only yesterday (July 8th), the result of which cannot be known for two or three weeks. Yesterday also the following letter reached me from Rio de Janeiro, Brazil, dated June 10th, 1886:—

"DEAR SIR,—In THE LANCET of May 8th, I note your letter with reference to the cure of spina bifida by means of the iodo-glycerine fluid. I beg to place at your disposal the following notes of a successful case I had, which was treated solely by your method: Henrique M——, born March 4th, 1885, with a lumbar spina bifida, about the size of a half orange. A strong well-made child, with no other deformity. On March 12th, tumour *in statu quo*. I tapped it with a fine trocar and cannula, and drew off about two drachms of fluid, and then injected about half a drachm of the fluid containing ten grains of iodine and thirty of iodide of potassium to one ounce of glycerine. On withdrawing the cannula I sealed up the puncture with collodion. No injurious effect followed. One week after, the operation was repeated, and likewise a third time. After each operation the coverings became more thickened and corrugated, until a fortnight after the third tapping no trace of fluid was present, and the tumour was reduced to a flattened, fleshy, wrinkled mass. After a lapse of fifteen months it is still further diminished in size, and the child is as plump and lively as possible, showing no sign of weakness anywhere. I regret that my experience of such cases is limited to this case only, but observing your letter above mentioned, and especially the quotation from the *Dublin Medical Journal*, I consider it my duty to inform you of this, another case, in which your method has proved eminently successful.

"Believe me, dear Sir, yours very sincerely,

(Signed) "W. LOUDON STRAIN, M.B. GLAS.,

"Late Resident Assistant, Glasgow Western Infirmary.

"James Morton, M.D."

I may be allowed to call attention to the early age at which this case was treated, of which I entirely approve, and to express the pleasure which such success in the hands of others always gives me.

With thanks to Dr. Strain, I am, &c.,

Glasgow, July 9th, 1886. JAMES MORTON.

THE CHARTERHOUSE SCHOOL.

To the Editor of THE LANCET.

SIR,—The correspondence in *The Times* during the past week respecting diphtheria at the Charterhouse School cannot fail to greatly interest the medical profession. A great deal of an unpleasant nature has come to the surface, but, judging from Mr. Carritt's letter in Wednesday's *Times*, much more lies behind yet unrevealed, which he promises to disclose if the governors of the Charterhouse School will hold an inquiry into the matter. So far as we can now judge, when the boys were going home for their exeat on June 26th, Mr. Carritt was told that measles existed in the school, and was asked if his son might come

home. When the lad arrived he told his father there were two cases of diphtheria in Mr. Girdlestone's house; one of these died in three days, the other remaining ill till he was able to be moved within the past seven days. The head master, in his letter on Monday, acknowledges these two cases, and says that seven others had sore-throats with diphtheritic tendency. The question raised by Mr. Noble Smith in *The Times* on Wednesday is the chief one, and really means "Who is to blame?" As undoubted diphtheria existed at the time of the exeat, why were not the parents told before the boys went home on June 26th? Why were not these two cases, at any rate, moved to the sanatorium? It appears terrible that they should lie ill on the same floor as the cubicles.

I hear that a consultant was called in some days before the *exeat*, and has been there several times. How is it he has not told us if he found the house free from any suspicion of bad drainage? Did he find the arrangements made for nursing and for preventing the spread of the disease all satisfactory! Did he think only two boys had plain diphtheria? and how many cases of sore-throat, simple or suspicious, did the medical officer report as having occurred in the past few months in the school? Was it by his advice parents were not told of the existence of diphtheria? All these are questions which require replies; and a letter from a consulting physician would set many anxious minds at rest.

Mr. Noble Smith thinks Dr. Clarence Haig-Brown had not full power to enforce his regulations, because the boy was not removed from Mr. Girdlestone's house, and inquires if his recommendations were carried out. Let us hear what those recommendations were, as it is plainly hinted in his letter that there was divided authority.

The medical profession cannot discuss the head-master's treatment of Mr. Carritt; but the other questions raised, especially the sanitary arrangements and the medical management, must interest all of us.

I am, Sir, yours obediently,

July 15th, 1886. M.D., AN OLD PUBLIC SCHOOL MAN.

REMARKABLE CONCOMITANT OF HYDROCELE-TAPPING.

To the Editor of THE LANCET.

SIR,—On reading one of your annotations of July 3rd on a "Remarkable Accident while Tapping a Hydrocele," I thought probably it would not be uninteresting to record the following case, as I am in the same position as M. Loumeau in not finding an example of a similar kind in medical literature.

The Rev. ——, who lived in the north of Devon, regularly visited me twice yearly for more than twenty years for the purpose of being tapped for hydrocele of the right side. His visits in my neighbourhood being always very short, he preferred merely to be relieved of the fluid, and generally about a pint of serum was removed at each tapping. He had an inguinal hernia of the same side. About ten years ago, in the month of July, this gentleman came to me as usual, and, on passing the trocar, to my astonishment only about a tablespoonful of fluid escaped. I concluded I had penetrated a cyst, and might have injured the tunica albuginea. As he was going into Cornwall direct from my house, and would return in three days, I advised no further procedure until he came back. The tapping occurred on a Saturday. On the following Tuesday, he told me that on reaching Penzance he began to feel a stiffness in his right knee, which became painful, but not sufficient to prevent him from helping in clerical duties on Sunday. Large effusion in the joint followed—in fact a perfect hydrops articuli; but I found that the hydrocele had entirely disappeared. Three days' rest, with fomentations &c., quickly relieved the joint. About six months after this, my patient was about to pay his usual visit for the tapping, when, on driving to the nearest railway station, his horse stumbled and he was thrown out of his gig, injuring his right knee, which became very swollen. Again the hydrocele disappeared.

This gentleman has recently died at an advanced age, but for several years after the accident of the gig I used the trocar for his relief. I have mentioned this case to several eminent provincial surgeons, and have been told that, as far as they knew, it was unique.—I am, Sir, yours truly,

EDWIN J. WORTH, M.R.C.S. Eng., &c.

Millbrook, Cornwall, July 7th, 1886.

IRELAND.

(From our own Correspondent.)

THE VICE-PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS.

MR. FITZGIBBON, surgeon to the City of Dublin Hospital, who retired from the contest for the vice-presidency last June in favour of Mr. Corley, considering this gentleman to have prior claim on the electors, will be a candidate for the vice-presidency in 1887. It is rumoured that Mr. Fitzgibbon will be opposed by a gentleman belonging to the hospital with which he is connected.

REPRESENTATION OF THE UNIVERSITY OF DUBLIN IN PARLIAMENT.

Both the late representatives have been re-elected by overwhelming majorities. Although every exertion possible was used by the defeated candidates, they were only able, out of a constituency of some 4000 electors, to obtain fifty-five and fifty-six votes respectively.

REMOVAL OF A FOREIGN BODY IMPACTED IN THE THROAT FOR THREE MONTHS.

A little girl aged three years was recently admitted into the Adelaide Hospital, under the care of Mr. J. Kellock Barton. It appeared that about three months previously the shuttle of a sewing machine had got impacted in her throat close to the epiglottis, and latterly had caused symptoms of distress. On last Friday Mr. Barton tried to remove it with a throat forceps, but from the nature of the foreign body the attempt was unsuccessful, and the next day an operation was undertaken. An incision was made on the left side of the neck passing close to the corner of the hyoid bone, and after a difficult dissection the shuttle was removed. The parts were brought together by sutures, and since the operation the little patient has progressed satisfactorily.

MATER MISERICORDIÆ HOSPITAL.

The new wing is now nearly completed, and is expected to be finished early in August. It forms the third side to the hospital, and will comprise three floors. The total expenses incurred will amount to about £20,000.

LIMERICK WORKHOUSE: CRUELTY TO AN INMATE.

At the Limerick Assizes last week, Mary Gurney, a night nurse in the female department, and Mary Fitzgerald, a pauper assistant, were charged with killing, on the 29th of April last, one Margaret Bourke, an old blind inmate of the Limerick Workhouse Hospital. Evidence was given that the deceased fell out of bed and was allowed to remain on the floor for a considerable time before the accused put her back, and when they did her hands were tied together. Bourke died the next morning, and the jury having found the prisoners guilty, Mr. Justice Johnson sentenced Gurney to two months' imprisonment, and Fitzgerald, who had been some time in prison, to three weeks.

It is rumoured that Dr. F. MacCabe, medical adviser to the General Prisons Board, has been appointed Inspector of Reformatory and Industrial Schools, Ireland.

Dublin, July 13th.

PARIS.

(From our own Correspondent.)

THE RELATION OF ORCHITIS AND OVARITIS TO AMYGDALITIS.

DR. JOAL, one of the physicians of Mont-Dore, has lately published a work in which he makes a very important contribution to pathology, in showing the relation that exists between orchitis and ovaritis on the one hand, and amygdalitis on the other. Dr. Joal makes out that during an attack of amygdalitis complications in the genital organs may arise as in other general affections. When these supervene, they are not the result of metastasis, as was formerly supposed, but they are all three produced by one and the same cause—an infectious condition of the economy,—the three maladies named being manifestations of that condition. Lasègue, Bouchard, Landouzy, and Siredey considered that

amygdalitis was the expression of a general malady of an infectious nature, but they looked upon orchitis and ovaritis as complications. Dr. Joal, however, proffers the explanation that, the organism being primarily contaminated, bacterian explosions are produced in a secondary manner in divers organs—the tonsils, ovaries, and testicles. The author does not admit the pretended physiological relations that were said to exist between the tonsils and the genital organs, adding that if the tonsils and the testicles are affected at the same time, it is generally during adolescence, at the age when these glands present a functional hyper-excitability. The author founded his arguments on fourteen cases of orchitis, or of ovaritis, which came under his own observation, and which manifested themselves under the influence of the tonsillitic affection, which, in its turn, was the result of an infectious condition of the organism, as mentioned above. This conclusion was arrived at as the genital symptoms could not be attributed to the propagation of a previously existing hyperæmic condition of the neighbouring organs—urethra, bladder, and uterus; nor could they be attributed to traumatism, excessive fatigue, or to menstrual or other genital disorders. Neither could they have been traced to the influence of any general affections, such as typhoid fever, variola, rheumatism, or purulent infection, which are apt to provoke orchitis or ovaritis. The etiology of tonsillitic ovaritis and orchitis has been well studied, and the symptomatology of these diseases has also been well described by the author. The genital manifestations, he says, are independent of the gravity of the tonsillitis, showing themselves ordinarily at the moment when the tonsillitic phenomena are on the decline. The complications, which are rare in childhood, appear principally in adolescence; they are generally unilateral. Orchitis ordinarily terminates in resolution; in one case, however, there was suppuration; in another the testicle was atrophied.

M. PASTEUR.

That cases simulating hydrophobia may now and then occur is not to be wondered at, owing to the sensation caused by M. Pasteur's anti-rabic inoculations. At a recent meeting of the Council of Public Hygiene Dr. Dujardin-Beaumetz gave an account of two such cases that were observed at the Hôtel Dieu. One of the patients admitted to the hospital on the 24th of May presented all the symptoms of alcoholic delirium, but left the hospital two days after, quite cured. He had been bitten fifteen days previously by a dog that was not mad. In one of his fits of delirium, the patient tried to bite the people about him. It was this circumstance that led to the supposition that the man was hydrophobic, but Dr. Dujardin-Beaumetz stated that in all the cases of hydrophobia that came under his observation he never saw hydrophobic patients attempt to bite people about them, and he believed that whenever such symptoms are produced, we have to do, not with hydrophobia, but with alcoholism. He remarked that last year, at the Lariboisière Hospital, a male patient who was affected with rabies bit the attendants, but he was at the same time under the influence of alcoholism, and it was to this latter condition that his tendency to bite must be attributed. The second case was that of a man who was taken to the Hôtel Dieu, stating that he had been bitten some time ago by a dog, and that he felt the symptoms of hydrophobia coming on. It was found, however, that he was simply suffering from some gastric trouble, and four days after his admission he left the hospital perfectly cured. The author observed that this individual had the year previously been admitted to the Necker Hospital, where he also simulated hydrophobia for some days. In concluding his report, Dr. Dujardin-Beaumetz stated that since the 1st of January, 1886, there have been in the department of the Seine ninety persons bitten by dogs known to have been manifestly mad, and that only one of these persons, who had not had recourse to the inoculations practised at the laboratory of M. Pasteur, died from hydrophobia. On this the author makes the following remarks: "One cannot bring this remarkable fact too much to light, in presence of the incessant attacks that are directed against the method of our illustrious colleague. On the one hand, the absolute immunity of all the persons who, after having been bitten by mad dogs during this first half-year, had recourse to the inoculations, and, on the other hand, the verification of only one death, that of the individual who would not submit to this method of treatment, are striking proofs of the certainty and of the efficacy of these inoculations. So that it will not be too much to remind the Parisian population that it will for the future find in these inoculations, when they are opportunely practised, a sure protection against rabic accidents." Dr. Dujardin-Beaumetz added that, according to information that reached him, there had been in London since the 1st of January last seven deaths from hydrophobia. In 1885 the number of deaths from the same disease in London amounted to twenty-six. The number of deaths from hydrophobia in the department of the Seine during the same year was twenty. While on the subject of M. Pasteur's anti-rabic inoculations, I may note certain modifications that have been introduced by him since he first commenced them, and which I have taken from Dr. Grancher's lecture, reported in THE LANCET of last week. The rabbits to be inoculated are put under chloroform during the operation of trephining and inoculation, which are effected on aseptic principles. The wound, instead of being washed out with carbolic acid, which would destroy the virus, is simply moistened with the acid. The bottles in which the spinal cords are preserved are now closed at the lower opening by a piece of cotton-wool, instead of having a tap, as formerly. M. Pasteur practises only ten inoculations, instead of thirteen, as in the case of Meister, his first patient. The inoculations are performed once every day, thus leaving an interval of twenty-four hours after each inoculation. The first inoculation is made with a spinal cord that has been preserved fifteen days, the second with a cord fourteen days old, and so on. The last inoculation is made with a cord six days old. M. Pasteur inoculates from cords which have been preserved for only from one to five days those cases where the wounds resulting from the bites are especially dangerous, on account of the region they occupy, their number, or the death of tissue injured.

Paris, July 13th.

THE SERVICES.

SURGEON-MAJOR EVATT, medical officer to the Royal Military Academy, will vacate his appointment on the staff of that institution next week, and will be succeeded by Surgeon-Major Maxham.

ADMIRALTY. — The following appointments have been made:—Fleet Surgeon Henry F. Norbury, C.B., to the *Impregnable:* Fleet Surgeon Robert H. More, M.D., to Plymouth Hospital; Surgeon Jas. L. Smith, to the *Starling;* and Surgeon and Agent Patrick C. Hockey, to Kilkee.

ARTILLERY VOLUNTEERS.—1st Inverness-shire: Surgeon A. Sclanders, M.D., is granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Essex Regiment: Acting Surgeon M. H. Grattan resigns his appointment.—1st Sussex: Surgeon Willoughby Furner resigns his commission; Acting Surgeon Douglas William Giffard to be Surgeon.—2nd Volunteer Battalion, the Royal Warwickshire Regiment: Surgeon Clement Dukes, M.D., is granted the honorary rank of Surgeon-Major.—2nd Wiltshire: Acting Surgeon E. N. Carless, to be Surgeon.—2nd Volunteer Battalion, the Worcestershire Regiment: Surgeon W. S. Batten and Honorary Assistant-Surgeon S. Roden, M.D., resign their commissions.

THE VOLUNTEER MEDICAL STAFF CORPS.—Surgeon J. H. Casson is granted the honorary rank of Surgeon-Major.

THE DEAF AND DUMB ASYLUM.—An election of twenty children to the benefits of this institution took place on the 12th inst. The asylum was founded in 1792, and since that date 4743 children have been admitted, leaving 319 now in the institution. Since the year 1811, 1848 boys and girls have been bound to various trades, at a cost of upwards of £17,276. The committee have decided to enlarge the branch asylum at Margate, and they are rebuilding the asylum in the Old Kent-road. At Margate, too, a separate building is being erected for an infirmary.

BELFAST MEDICAL STUDENTS' ASSOCIATION.—The inaugural meeting of this Association was held on the 13th inst., when there was a large attendance of students and medical men of the town. The object of the Association is to promote the interests of the Belfast medical students as regards their professional training.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners, held on the 5th inst. and following days, the undermentioned gentlemen passed the Third Professional Examination of the College:—

John Abbott, James J. Behan, Edward C. Brabazon, Thomas Carr, Thomas R. Cowen, Stafford M. Cox, Eugene Glynn, Arthur S. Goff, Richard J. Hewitt, George L. Johnston, Leonard Kidd, Victor B. Ludlow, Charles C. Lyons, John J. McNaboe, James C. O'Donnell, Pierce H. Power, John H. Reynolds, Michael Shanley, Arthur E. Sprowle, John Stewart, Timothy T. Teahan, James Traut.

Fifty-nine candidates entered for examination; seven withdrew, one was absent, and twenty-five were stopped.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 8th inst.:—

Agnew, Edward Dalton, Soho-square.
Armstrong, William, Limefield, Kersal, Manchester.
Blake, William Henry, Brondesbury Villas, Kilburn.
Drinkwater, Charles, Memorial Cottage Hospital, Mildmay.
Smith, Percival, Hanley-road, Crouch-hill.

ON the 9th inst. Princess Christian visited University College Hospital and inspected several of the wards.

THE annual inspection of the Leavesden Asylum for Imbeciles by the managers of the Metropolitan Asylums Board took place on the 10th inst.

THE prizes gained by the students of the Bristol Medical School were distributed on the 12th inst. by the Rev. S. W. Wayte, who pointed out that the school was almost, if not quite, the earliest provincial school of medicine in the country.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund held on the 13th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £67 was distributed among the several applicants.

DR. GEORGE T. STEVENS, of New York, has been awarded the prize offered by the Académie Royale de Médecine of Belgium for the best elucidation, by clinical facts and by experiments, of the Pathogeny and Therapeutics of Diseases of the Nervous Centres, and especially Epilepsy.

THE CONDITION OF KINGSTON-ON-THAMES, from a sanitary point of view, is the subject of unfavourable comment in the local press. The state of the public sewers in the borough, especially, would appear to stand in need of immediate attention.

MR. ROBERT ROGERS, L.K.Q.C.P.I., L.R.C.S.I., of Falmouth, Jamaica, expired suddenly whilst bathing on the 11th ult. The deceased had practised for upwards of fifteen years in Jamaica, and was highly respected by those with whom he came in contact.

"THE Effects of Tobacco on the Health of Men of Letters, and its Influence on the Future of French Literature," is the theme to be discussed in a series of essays, for the best of which the French Society for the Prevention of the Abuse of Tobacco offers a prize of 1000 francs.

THE combined districts of Leamington, Warwick, Kenilworth, and other places in the Warwick Union, have decided on a site for an infectious hospital. Hitherto a building at the Warwick Workhouse has been resorted to for this purpose, but its Poor-law connexions have materially interfered with its proper use.

PROFESSOR CROCQ OF BRUSSELS.—The senior medical students of the University of Brussels have just presented Professor Crocq with a work of art, "Le Penseur," after Michael Angelo, as a mark of their appreciation of the unceasing kindness with which he has assisted them in their university and clinical studies.

AT the tenth anniversary meeting of the Sanitary Institute of Great Britain, held on the 8th inst. at the Royal Institution, Albemarle-street, Dr. T. Whiteside Hime, medical officer of health for Bradford, delivered an address entitled "Pasteur and Preventive Inoculation against Zymotic Diseases." A vote of thanks to Dr. Hime for his address was proposed by Professor Corfield, and carried.

A SHEFFIELD police-constable and a little girl, having been bitten by a dog suffering from rabies, left on the 10th inst. for Paris to place themselves under the treatment of M. Pasteur.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The annual general meeting will be held in the rooms of the Medical Society, Chandos-street, Cavendish-square, on Aug. 9th, 1886, under the presidency of G. H. Savage, M.D. In the evening the dinner will take place at "The Ship," Greenwich, at 7 P.M.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY. At the meeting of the Committee of Management of this institution held on the 3rd inst., it was reported that during the first three months of the present year only 280 in-patients were admitted to the hospital, or 56 fewer than had been received during the corresponding three months of the previous year; whereas 347 patients were received during the second three months, bringing the total of the half-year up to 1127, or 11 in excess of the first half-year of 1885. The number of out-patients received was 71. The financial condition of the hospital is fairly satisfactory.

EARLSWOOD ASYLUM FOR IDIOTS.—The annual report of the committee of this institution, which has just been published, states that the income of the past year has fallen short of the previous year by some £2600. The report of the medical superintendent (Dr. Cobbold) is of a satisfactory character, and shows that there were in the asylum on March 31st 378 males and 188 females. The number of new patients admitted was greater than for several years past; this is chiefly due to the fact that no less than forty were elected in April and October. A decided improvement is reported in the class of cases admitted.

TEMPERANCE CONGRESS.—The British and Colonial Temperance Congress began its sittings on the 14th inst. The object of the Congress is to receive information, through written papers and oral communications, regarding (1) the extent of drinking habits in the colonies and dependencies of the British Empire; (2) the regulations in force in those localities for restricting or prohibiting the drink traffic; and (3) the results of efforts put forth by temperance organisations, churches, Sunday schools, educational boards, and other public bodies, for the promotion of total abstinence from intoxicating liquors. The Bishop of London presided, and there was a large attendance at the opening meeting. Papers were read by Dr. Pringle, the Rev. R. H. Bullock, Mr. Gunn, Mr. Barton, and others.

THE magisterial examination into what is known as the Ashton poisoning case was concluded at Stalybridge on Wednesday. The prisoners, Mary Ann Britland and Thomas Dixon, were accused of having caused the deaths of three persons by administering poison. Evidence was given that Dixon's wife and Britland's husband and daughter died within a short time after a brief illness. All displayed symptoms of poisoning. The bodies were exhumed and subjected to analysis, and were found to contain strychnine. It was proved that the female prisoner had made several purchases of "Vermin Killer," one of the ingredients of which is strychnine. The theory of the prosecution was that Dixon's wife and Britland's husband had been removed to make way for a union between the prisoners. The magistrates discharged Dixon, and committed the female prisoner for trial on the capital charge.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARRITT, G. LACY, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Johnson Hospital, Spalding; and Medical Officer of Health for the Spalding District, vice C. K. Morris, resigned.

BRODRICK, H. EDWARD, M.R.C.S., has been appointed Resident Clinical Assistant to the East London Hospital for Children and Dispensary for Women, Shadwell, E.

BUTLER, FRANCIS WILLIAM, M.R.C.S., L.S.A., has been reappointed Surgeon to the Hearts of Oak Society for the Brighton District.

CARTER, ROWLAND WIMBURN, M.R.C.S., L.S.A., has been appointed Surgeon to the Weymouth and Dorset County Royal Eye Infirmary, vice Simpson, resigned.

CUFF, ROBERT, M.B.Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Scarborough Union.

FAIRBAIRN, J. BINNIE, M.B.Glas., has been appointed House-Physician to the Glasgow Royal Infirmary.

HEWITT, FREDERIC, B.A., M.D.Cantab., has been appointed Instructor in Anæsthetics at the London Hospital.

LEECH, ARTHUR H., L.S.A., has been appointed Medical Officer for the Second District of the Stow Union.

OGLE, ARTHUR W., M.R.C.S., L.R.C.P., L.S.A., formerly Obstetric House-Physician, has been appointed House-Physician to the Middlesex Hospital.

PERRY, R. C., M.A., M.B.Cantab., M.R.C.S., has been appointed House-Surgeon to the London Hospital.

PURDON, RICHARD J., M.D., M.Ch.R.U.I., has been appointed Visiting-Physician to the Belfast District Lunatic Asylum, vice Henry MacCormac deceased.

SCOTT, W. SAWERS, M.B., C.M., has been appointed Resident House-Surgeon to the Clinical Hospital, Manchester.

WARE, GEORGE STEPHEN, M.R.C.S., L.R.C.P., L.S.A., formerly House-Physician, has been appointed Obstetric House-Physician to the Middlesex Hospital.

WETWAN, WILLIAM A., M.R.C.S., L.S.A., has been appointed Medical Officer for the Workhouse and First District of the Bridlington Union.

Births, Marriages, and Deaths.

BIRTHS.

ATKINSON.—On the 7th inst., at Abbey-hill, Kenilworth, Warwickshire, the wife of Miles C. Atkinson, M.D., of a son.

CHETWOOD.—On the 12th inst., at King-street, Finsbury-square, the wife of William Chetwood, M.R.C.S., of a daughter.

FREEMAN.—On the 3rd inst., at Pangbourne, Reading, the wife of W. T. Freeman, L.R.C.P.Lond., of a daughter.

JOYNT.—On the 18th ult., at Marine-gardens, Hanover-street, Kingston, Jamaica, the wife of Surgeon-Major H. W. Joynt, Army Medical Staff, of a son.

LEWINSON.—On the 7th inst., at 32, New-street, Smethwick, the wife of Louis Lewinson, M.D.Berl., of a son.

PIDCOCK.—On the 6th inst., at Downshire-hill, Hampstead, N.W., the wife of G. Douglas Pidcock, M.A., M.B.Cantab., of a son.

POWELL.—On the 3rd inst., at the Borough Asylum, Nottingham, the wife of Evan Powell, of a son.

RICHARDS.—On the 11th inst., at the County Asylum, Hanwell, the wife of J. Peeke Richards, Medical Superintendent of the Female Department, of a daughter.

MARRIAGES.

BIRCH—KINSMAN.—On the 7th inst., at the Parish Church, West Derby, Richard Birch, M.R.C.S., L.R.C.P., to Anne, only daughter of Major W. A. Kinsman, of The Tower, Sandfield-park, West Derby.

BOWHAY—WOODD.—On the 10th inst., at St. John's, Penge, Albert Bowhay, L.R.C.P.Lond., of Gunnislake, Cornwall, to Edith, daughter of C. G. Woodd, Surgeon, of Penge.

FELL—RICHMOND.—On April 26th, at St. Paul's Cathedral, Wellington, New Zealand, Walter Fell, M.D., of University College, Oxford, and St. Thomas's Hospital, London, to Margaret, third daughter of Mr. Justice Richmond, of Wellington.

FOX—BABINGTON.—On the 8th inst., at the Church of the Holy Trinity, Ilfracombe, Arthur E. W. Fox, M.B., to Emily Frances, youngest daughter of the Rev. Thomas A. Babington, of Cossington, Leicestershire.

HAYWARD—KENDRICK.—On the 6th inst., at All Saints', Brixham, Arthur Ernest Hayward, M.R.C.S., to Catherine Eames, youngest daughter of W. G. Kendrick, of Hillside, Brixham.

HEWER—EVERARD.—On the 13th inst., J. Langton Hewer, M.B., B.S., F.R.C.S., eldest son of John H. Hewer, of 33, Highbury New-park, to Annie M. Everard, eldest daughter of the Rev. George Everard, M.A., Vicar of Christ Church, Dover.

INGOLDBY—WILCOXON.—On the 13th inst., at Albany, W. Australia, Frederick John Ingoldby, M.R.C.S., L.R.C.P., to Annie May, elder daughter of C. Wilcoxon, of Barnes.

TILLY—PRATT.—On the 7th inst., at Holy Trinity, Finchley-road, Alfred Tilly, L.S.A., to Emma Marian, eldest daughter of the late James Boulton Pratt, of Earl's-terrace, Kensington, and the Stock Exchange.

DEATHS.

DUNN.—On May 8th (after a few hours' illness), at Hastings, New Zealand, George Dunn, M.D., J.P., of London, and formerly of Doncaster.

FURNIVALL.—On May 27th, at Hutton, Somerset, William Furnivall, M.R.C.S.Eng., L.S.A., aged 80 years.

GARDNER.—On the 17th ult., at Bareilly (by a fall from his horse), Edward Barton Gardner, Surgeon-Major, H.M.'s Indian Army, Civil Surgeon of Bareilly.

SPEER.—On the 9th inst., at his residence, Salisbury-street, Liverpool, Joseph Speer, L.R.C.P.Ed., L.R.C.S.I., aged 57.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Letters requiring notice must be authenticated by the name and address of the writer.

We cannot undertake to return MSS. not used.

TREATMENT OF ECZEMA.

DR. MED. HAGENA writes to call attention to the benefit of wearing buck leather underclothing, especially by those who may be suffering from eczema. The advantages, he points out, attending the use of that material are that it is softer than cotton or wool, that it diffuses a more equable warmth, and that it therefore averts irritation of the sensitive skin, and assists the process of healing to be set up by the application of an unguent composed chiefly of salicylic acid and lanoline (the Salicylpflastermull of Dr. P. G. Unna).

Mr. Jas. Turton.—Yes, by Shepherd. But perhaps the best book to consult is the Manual for the Medical Staff Corps, published by Messrs. Clowes and Son, Charing-cross, which contains all necessary information for training stretcher bearers and bearer companies.

SYPHILITIC PHARYNGITIS.

To the Editor of THE LANCET.

SIR,—I have a lady patient who has for over twenty years suffered from tertiary syphilis. She has at present a most painful dry pharyngitis, the mucous membrane is dry and sticky, here and there coated with a thick, foul, yellow mucus. This causes much coughing and great difficulty in swallowing anything but fluids. Antisyphilitic treatment, which she has had for many years, now does her no good in this present ailment. An inhalation with a Seigel's spray containing terebene nd pinus sylvestris oil does relieve her, only temporarily however, although it has in great measure healed some nasty deep fissures on both lips and left angle of the mouth. I should esteem it a great kindness if any of your many readers who may have had a similar case to deal with would suggest a line of treatment which might possibly soothe a miserable existence.

I am, Sir, yours faithfully,

July 13th, 1886. MED. DOC.

PRIMARY UNION AFTER SUPRA-PUBIC CYSTOTOMY.

To the Editor of THE LANCET.

SIR,—In your issue of July 3rd, Mr. Parker referred to primary union of the wound after supra-pubic cystotomy (in his case) as probably unique. Mr. Parker will find a similar experience recorded by Dr. L. S. Pilcher in the "Annals of Surgery," February, 1886.

I am, Sir, yours obediently,

Llanberis, N. Wales, July 6th, 1886. J. T.

A DAY IN THE COUNTRY FOR POOR CHILDREN.

MR. G. HOPKINS, Honorary Superintendent of the East London Mission, 263, Cable-street, St. George's, E., and Mr. A. Alfred Knight, Treasurer of the Hackney Mission, whose address is Knightsville, Lewisham High-road, London, both wish us to commend their schemes for giving poor children a day in the country. All such schemes should be helped by those who can help. When we are all devising holidays for ourselves and children, we should be mindful of those whose means admit of no such pleasure, and many of whom have never seen hay-making or the sea.

An Old Subscriber.—The registration of such foreign degrees as those described by our correspondent cannot take place till June, 1887.

Dr. L. Petit (Paris).—We cannot give a reply until a copy of the journal is before us.

CIRCUMCISION UNDER THE INFLUENCE OF COCAINE.

To the Editor of THE LANCET.

SIR,—I was called on May 29th, 1886, to see J. M——, a boy aged eight years, living at Portland-road, Notting-hill. I found him suffering from paraphimosis, and recommended circumcision. As the parents were quite willing, I operated on the following day (May 30th), having determined on using cocaine, as the boy's heart is diseased. Accordingly, a few minutes before the operation I injected, with a hypodermic syringe, about four drops of a 10 per cent. solution of hydrochlorate of cocaine through the prepuce, close to the corona penis, repeating this on the other side of the corona, and also injecting another five drops through the under portion of the prepuce, still keeping close to the base of the glans. I then directed the mother to hold the foreskin tight for a few minutes, in order to thoroughly anæsthetise—or "cocainise"—the mucous membrane of the prepuce. I then proceeded to circumcise the boy in the usual manner, having first placed a cloth over his eyes. After removing the redundant prepuce, I brought together the skin and mucous membrane with nine catgut sutures. The boy told me—and he is an intelligent lad—that he felt no pain at all, excepting during the insertion of the last two sutures, and then it was so slight that it did not cause him to cry out. I dressed the wound with carbolic oiled lint, and a good recovery was made. On the first evening the patient's temperature was 101·4°; next morning it was normal, and has remained so. The wound healed by first intention, excepting just close to the frænum; that had granulated, but is now quite well. The patient was in bed eight days. As has been observed, there was very little inflammatory œdema after the operation, this being due, in my opinion, to the astringent, as well as locally anæsthetic, property of cocaine. In all, I injected fourteen drops of the 10 per cent. solution, and there were no toxic effects produced.

I am, Sir, your obedient servant,

J. MITFORD ATKINSON, M.B. Lond.,
Medical Officer to No. 3 District, St. Mary Abbott's,
June 21st, 1886. Kensington.

DISTENDED HYMEN OCCLUDING THE VAGINA.

To the Editor of THE LANCET.

SIR,—I send you some particulars of a case at present under my care which may possibly be considered of sufficient interest to merit insertion in the columns of your journal.

On June 8th I was called to see Ada P——, aged thirteen, who was said to have been ill some two or three days, complaining of pain and difficulty in micturition. I found the child in intense pain, and was told that she had not passed urine for eight or ten hours previously to my visit. I examined the abdomen, which was extremely tender to the touch, and found a largely distended bladder. On examining the genitals I discovered a rounded tumour about the size of a small orange apparently protruding from the vagina, but which, on closer examination, proved to be a sac, the walls being formed by a highly distended hymen, which entirely occluded the vaginal orifice. I incised the membrane (which was thick and fleshy), thus affording exit to about half a pint of dark sanguineous fluid of the consistence of treacle. The child obtained immediate relief, and voided the contents of the bladder without difficulty shortly afterwards.

The above condition was wholly unsuspected prior to my visit, although the mother had wondered at the absence of the menstrual flow, the child having regularly presented other symptoms usually observable during the performance of the menstrual function, for some six or eight months. Believe me, Sir, yours faithfully,

Bedale, June 10th, 1886. THOS. HORSFALL.

MR. A. B. SIMPSON AND THE BIRMINGHAM GUARDIANS.

To the Editor of THE LANCET.

SIR,—May I be permitted to mention through your columns that the Midland Centre of the Medical Defence Union is actively engaging itself in preparing a petition against the authorities' decision in this matter, which it is hoped will be signed by all the medical practitioners and chief ratepayers of the district. I hope to be able to forward you a copy of the petition in due course.

I am, Sir, obediently yours,

CHARLES F. RIDEAL, General Secretary.

The Medical Defence Union (Limited by Guarantee),
17, Bedford-row, W.C., July 13th, 1886.

THE HEAT AND RAINFALL OF INDIA.

A MEMORANDUM has been drawn up by Mr. H. F. Blandford, Meteorological Reporter to the Government of India, which is intended to accompany charts of temperature and rainfall of the country. From this report it appears that the hottest region is really the eastern coast of the Peninsula from Vizagapatam southwards and the plains of the Carnatic and Northern Ceylon. In the Peninsula, or intra-tropical India, except as modified by the elevation of the country, the temperature increases steadily from the coast inland; and the west coast is cooler than the east coast. Scinde and Rajputana are the driest portion of India. May is the hottest month of the year in the greater part of the country, the chief exception being in the Punjaub and Scinde, where, owing to the later setting in of the rains, June is the hotter month. The mean annual rainfall of the whole of India proper is about forty-two inches, varying from an extreme of nearly 500 inches at Cherra Poonjee to about three inches at Jacobabad in the extreme west. Those provinces with an average rainfall of more than fifty inches, and an average variability of less than 13 per cent. on either side of that average, enjoy practical immunity from famine.

SHIP SURGEONS.

To the Editor of THE LANCET.

SIR,—Mr. W. T. Harris, who writes on the above subject in your last week's issue, appears to have overlooked the fact that the letter of "M. A. P." to which he refers had reference to surgeons on Atlantic steamers, not to steamers going Southern voyages. I do not know any North Atlantic steamship line on which the surgeons have "absolute control of their own department." I speak from an experience of over three years. Take, for instance, the daily sanitary inspection of the steerages; this is conducted by the captain, yet when from bad weather or other causes the captain cannot leave the bridge he hands this duty over to the purser, not to the surgeon. Again, take the ships' hospitals; these ought surely to be considered part of the surgeon's department, yet there are few of the Atlantic steamships on which the hospitals are under the surgeons' control; they are constantly used as sleeping berths for stewards or others, and put to various other uses during a voyage, although the law requires that they be kept exclusively for the purpose for which they are intended, and infringements of this law are punishable by heavy fines: yet when have any of these fines been inflicted? If a surgeon mentions these or other infringements of the Board of Trade regulations in the report he has to send to the Emigration Office after each voyage he probably loses his appointment, and his report is very unlikely to reach its destination, as in most of the companies these reports have to be left open and sent to the steamship company's office for approval before being forwarded to the Emigration officer. As to vaccination fees being "a matter of agreement with a company beforehand," in the North Atlantic lines there is never any question about vaccination fees, as these vaccinations are done in compliance with a United States Government regulation, and average 8 or 10 per cent. of all steerage passengers carried. Every steerage passenger has to be examined by the surgeon, who gives to each a printed certificate of vaccination, signed by himself, and vaccinates any who either have not been previously vaccinated or in whom the vaccination marks have become indistinct. As many of these ships carry sometimes up to 1000 steerage passengers, this regulation involves an immense amount of trouble, particularly in bad weather, yet the surgeon gets no remuneration for this beyond his ordinary pay. As to "passengers' fees," an invitation to dine with the patient at his hotel after landing is the most usual way of acknowledging his indebtedness adopted by the Transatlantic passenger, if he considers it necessary to show his gratitude in any way. There are, of course, a few exceptions, but they are not often sufficient to materially augment the £8 or £10 per month which the companies consider sufficient remuneration for their medical officers.—Yours obediently,

Seacombe, Cheshire, July 12th, 1886. W. V. BARRÉ, L.K.Q.C.P., &c.

A READY EXAMINER.

THE following is extracted from *La Presse Méd. Belge*:—

IN THE EXAMINATION ROOM.—*Professor:* What would you do in the case of a uterine fibroma complicated with repeated and profuse hæmorrhages? *Candidate* (without hesitation and with confidence): I should perform oöphorectomy. *Professor:* Very good. I see you are well up in the surgery of the future. But what would you do with the fibroma? *Candidate:* I should leave it. *Professor:* Better still. But if the patient died? *Candidate:* I should bury her.

A Physician.—The case is not very clearly stated. There is a discrepancy as to the date on which the agreement was signed. If it is sent to us with correction, we shall be glad to express our opinion on it.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your reference to my article on the "Pharmacognosy of the Nitrites" in your issue of July 10th, p. 87, I observe my name is given as Mr. Armstrong; and, further, the article in question, which appeared in the *Pharmaceutical Journal* and Transactions, was not a lecture delivered in Edinburgh, but one written specially for the journal mentioned.

I have the honour to remain, Sir, your obedient servant,

University of Edinburgh, July 13th, 1886. G. ARMSTRONG ATKINSON.

THE OVERCROWDING OF THE PROFESSION.

To the Editor of THE LANCET.

SIR,—Any man who now embraces the medical profession as a means of support will (if he is not possessed of sufficient means or luck to get him a practice) find it a matter of no inconsiderable difficulty to get on. The present congested state of the medical market reminds me of a train which, already full, is still besieged by passengers in great numbers trying for places, with no porters to prevent the influx, and plenty of ticket offices invitingly open to give tickets. If legislation curb not by some wholesome laws this influx, and if gentlemen have not common sense, but take a ticket before they see a seat vacant, our lives will become a burden not only to ourselves but in all probability to the State. Trees are too old to be transplanted at forty years; and, unfit for any other calling, because untrained for it. Some of us will have to go under the fondling care of a board of guardians, and end our days mid the wrecks of idle or dissipated lives.

Lately in your pages have complaints appeared relative to the little respect medical men are treated with. One gentleman tells us he was placed with the riff-raff of the vessel at table; he is advised by another to humbug the steward with chaff and he will be treated decently—to play jester to the whilom cabin boy for the treatment due to his profession and services! Truly, a nice occupation for a medical officer. Some time ago a gentleman was offered a ticket for out-door relief by a guardian when he asked for a pension after a life-long service as Poor-law medical officer. These instances are the natural consequences of overcrowding. Anyone who takes the trouble can easily see that the supply is far greater than the demand, if the status of the profession is to be maintained. The Army and Navy have few places to offer, the mercantile marine could nearly sink their ships with the swarms of applicants. All that remains is assistancies—a life that would contrast unfavourably with a coachman's; the work is considerably harder, the pay about the same.

In conclusion, I would say to those who intend entering on the profession, Pause, and think before you pass the Rubicon! To our Legislature, Save us from ourselves, or we perish! Apologising for trespassing on your valuable space,

I remain, Sir, your obedient servant,

John-st., W., July, 1886. GEO. TANDY WILKINSON, L.R.C.S.I., &c.

Oceana.—The Midwifery Licence is obtainable at the Rotunda and Coombe Hospitals, and is recognised as a qualification by the Irish Local Government Board.

AN UNEXPECTED CAUSE OF NUMBNESS OF THE LOWER EXTREMITIES.

To the Editor of THE LANCET.

SIR,—About two months ago I was summoned to a patient who was stated to be suffering from paralysis. On arrival I found a man about forty-six years of age lying in bed, and complaining of numbness of the feet and calves of the legs, even up to the hips, without, however, any loss of either sensory or motor power—that is to say, there was partial suspension of sensory susceptibility in these particular localities. On visiting the patient next day, I found him up and dressed, and noticed a hesitancy in his manner of walking, especially when I asked him to cross the room with his eyes closed. In fact, when he attempted it I had to jump up from my chair to save him from the fireplace. I had attended this patient for years, and there was no history of syphilis to account for all this. His general health was good, and he was a man of abstemious habits. Could it be sclerosis of the posterior or lateral columns of the cord? Could it be due to some tumour or effusion pressing on the cord? Or could it be the result of some peripheral origin, seeing that the patient had frequent attacks of "cramp in the feet"? I asked myself all these questions, when it suddenly struck me that it would not be inappropriate to inspect the premises, which I did, and found, to begin with—which to my mind was quite sufficient, hygienically speaking, at all events—the w.c. completely blocked up, and running over; a state of things which had existed for six weeks. Now, this hardly seems to bear on the case in point; but if it be considered—as I found out—that pails are substitutes for imperfect or useless waterclosets, it comes within the range of possibility that the whole weight of the upper half of the body, at least in such a position and on such a sharp edge, would tend towards the "numbing" of the sciatic and its branches. Anyhow, this patient had to resort to this method of relieving himself, and, as he described it, with extreme difficulty on each occasion, the sharp edges of the pail adhering tenaciously to the skin over the gluteal region. I suggested that the closet should be looked to at once, and that the pail should be dispensed with. All this I took care was carried out, and about a week ago the patient came to my surgery to thank me. I may add that during the course of the treatment catheterism was necessary, as also were injections to unload the rectum.

I am, Sir, yours faithfully,

London, July 10th, 1886. T. HENRY WAGSTAFFE.

"PONDEROUS BREASTS."

To the Editor of THE LANCET.

SIR,—Your correspondent, "M.B.," will find in Billroth's Clinical Surgery (published in 1881 by the New Sydenham Society), page 209, a detailed account, with illustration, of a case of enormous hypertrophy of both mammæ, and of the course of treatment attempted to be pursued.

I am, Sir, yours obediently,

Penzance, July 11th, 1886. A. B. BERRY

FREE TRADE IN ALCOHOL.

SINCE the abolition of licensing in France, in 1880, drinking shops have enormously increased. So that France competes with England and Switzerland as an alcohol-consuming country. The Academy of Medicine recommends that the trade in alcohol should be made a State monopoly.

A. G. P.—1. Our correspondent can claim a fee for the midwifery case. Such a fee has frequently been allowed. Whether in any given case the law should be put in motion is a matter for the consideration of the practitioner himself. Law is sometimes a disappointing remedy.—2. It might be legally justifiable to stop the medicine in the case specified; but if the impecuniosity is real, it would be more kind to send it, with an intimation that the patient must apply for further help to the medical officer of the parish.

Mr. Thatcher (Dalston) is troubling himself unnecessarily. As we have already said, the names were obviously fictitious.

Cymro.—No.

PART OF TOOTH-PLATE IMPACTED IN THE ŒSOPHAGUS, AND AFTERWARDS PASSED NATURALLY.

To the Editor of THE LANCET.

SIR,—On June 9th, Mrs. D——, aged sixty-five, came to see me, complaining of great pain in the throat, and difficulty in deglutition, due, she said, to having swallowed a short time before part of her tooth-plate while eating a piece of cake. On manipulating the neck a little below the cricoid cartilage she complained of great pain, especially on the left side. Nothing could be felt in the œsophagus by the finger; but on passing a whalebone probe with a piece of sponge at the end it became arrested at about six inches of its length. A coin-catcher was passed several times, but unsuccessfully; but at last it caught the edge of the plate, and after a fair amount of traction the plate turned and the extractor loosened its hold. Various forceps were then tried, but unsuccessfully, occasionally catching it, but never with sufficient firmness to move it. As some time had been spent in these attempts to extract the plate, and the patient was becoming exhausted, she was allowed two hours' rest, when a further attempt proved equally unsuccessful. It was now decided to postpone any further attempt until the following day, and, if necessary to perform œsophagotomy, after the manner successfully carried out by Sir W. Mac Cormac in the case reported in THE LANCET of May 29th. On seeing the patient on the following morning, she said, to our consternation, that the substance had passed into the stomach. Great pain was still felt on swallowing, but the foreign body had evidently left its former situation. The patient was ordered to keep perfectly quiet and to live on farinaceous food, and it was decided to wait for further symptoms. She was visited daily. She still complained of great pain in the throat and inability to take much food. To our great relief, after a sojourn in the body of three days and three hours, it was passed naturally. It was about the third part of an ordinary tooth-plate, with an ugly hook projecting from one corner, which might have led to serious consequences.

I am, Sir, yours faithfully,

Lincoln, June 15th, 1886. W. J. CANT, M.R.C.S., &c.

DISLOCATION OF CRICOID CARTILAGE.

To the Editor of THE LANCET.

SIR,—I beg to forward you notes of a case which you may perhaps think of sufficient interest to admit into your columns.

During my voyage out here, by the courtesy of the ship's surgeon, I witnessed an accident which I believe to be of rare occurrence. A lady suffering from sea-sickness was confined to her berth, and the stewardess brought her some tea in a spouted feeding-cup. She was lying on her right side, and did not turn round, but simply rotated her head to the left to receive the tea, which the stewardess held to her lips. As she swallowed the first gulp she experienced a suffocating pain in the throat, and gasped for breath. The stewardess immediately sent for the ship's surgeon, who, on seeing the case, requested me to come. The patient was lying on her back, with her chin flexed on the sternum; the face and lips were of a dark purple colour, the hands cold, and respiration rapid, shallow, and of a hard and noisy type. In the middle line in front the lower margin of the thyroid cartilage was found to be unduly prominent, while under its left margin the left side of the cricoid cartilage could be felt tilted up. It was necessary to take immediate steps for the patient's relief; so (with tracheotomy instruments at hand in the event of their being required) the ship's surgeon stood at the patient's side and manipulated the cricoid, while I extended the chin and at the same time rotated the head towards the opposite side, when suddenly there was a sensation as of something giving way, followed by a fit of coughing and vomiting, at the end of which it was found that the parts had regained their normal position, and that the patient could breathe with comfort. The accident I believe to be due to the twisted position of the neck during the action of deglutition.

I am, Sir, yours very truly,

Calcutta, June 19th, 1886. F. C. BUTT.

ERRATUM.—In Mr. Gamgee's letter on John Hunter, page 98 of our last issue, for "Henry" read *Drewr* Ottley.

GUNTHORPE NATURAL MERINO HOSIERY.

IN our notice of this clothing material last week, the address of the manufacturers was given imperfectly. It should have been Messrs. Rogers, Black, and Co., Stoney-street, Nottingham, and 21, Aldermanbury, London, E.C.

Physician.—We wished for a complete and clear statement of all the facts and dates.

Dr. Althaus.—Very shortly.

AMERICAN MEDICAL SCHOOLS.

To the Editor of THE LANCET.

SIR,—It is by no means uninteresting to a medical man "abroad" to observe his own country and its institutions through the eyes of foreign authorities. And while we must confess to much that was questionable in the past, it appears at present that the case of medical education in the United States is hardly put with fulness—if, indeed, with fairness. As the effete doctrines of the early Church yet serve as the sceptic's best weapons, so now do the allegations which I here rehearse rise against the "American system." We are charged with "inadequate preparation," opening the schools to crude and undisciplined minds; with a "too short and narrow curriculum," giving insufficient and unbalanced foundation for so serious and important a superstructure; with "poverty of clinical advantages," committing students to an unpractical, and therefore untrue, view of their future duties; with "the full degree conferred by any of the too numerous colleges after such a course." Truly a sad catalogue of errors, if applicable now and generally to the institutions of any country. But a knowledge of all the circumstances will ensure material alteration in the scope of these charges, and a much closer approximation to the truth. Though I write without statistics at hand, and only from a general acquaintance with the facts acquired by long professional observation, I venture to state that more than half the American graduates have for many years gone out from the three great medical centres, New York, Philadelphia, and Boston, whither have gravitated for the same period the greater lights of the profession as practitioners, teachers, &c. These men, many of them of humble birth, self-taught, having elevated themselves to a great and noble success, do not forget their own origins, and are slow to place impediments in the way of those who have the same aspirations, the same difficult ascent to make. Hence, the moderate requirements of the preliminary examination to be followed in these schools by instruction not easily surpassed in breadth and accuracy, I am bold to say, whether it be didactic or clinical. Here hospitals are numerous and abounding in every variety of material. At Yale and the Cincinnati, Chicago, Michigan, St. Louis, and New Orleans schools the same is true, excepting the restrictions arising from moderate hospital accommodation, which will always vary with population. Here at least a third of the whole number of annual graduates receive their diplomas, and in most of these schools the final or "pass" examination covers the entire field of study, determining the solid acquirements of the student, rather than what he may have "crammed" during the weeks previous. In some cases the "State Medical Society" exercises a wholesome supervision, its delegates taking active part in the oral tests applied to scholarship. Post-graduate courses are often open to the more ambitious student, and to such practitioners of long-standing as may desire henceforth to restrict their work to special lines. To "graduate into a specialty" is not with us *en règle*. It is the "mushroom school" which gives rise to offences as rank in the nostrils of American as in those of foreign physicians. These spring up in the growing towns of the vast West, partly the offspring of local ambitions and rivalries, partly from a local demand for a not too costly medical instruction, made by the pupils and assistants of neighbouring practitioners, or by youths who labour two-thirds of the year to earn the means of defraying the cost of a winter's tutelage in medicine. Few of these ever graduate, and if they do few fail to seek their diplomas at a more legitimate fountain-head. The schools themselves meet with early decease, though their example and warning are not long heeded. It is true that all who graduate from these State-chartered schools receive the degree of M.D. and are styled "doctors," but in no country in the world does a man so soon find his proper level, whatever his profession or diploma. It is the absence of social caste, the subordination of influence to real merit, the general indifference to titles, the knowledge that, after all, success must be fought for, which make the American physician so oblivious of the initialed distinctions that obtain in England and elsewhere.

After all is said, in these days, when science is of common birth and acknowledges no single foster-mother, we may safely claim to be known by our fruits, and one may proudly point to the just and able criticisms of your own columns upon works of American origin for highest testimony to the value and volume of American professional attainment and culture. I am, Sir, yours faithfully,

Ilford, Essex. H. W. JONES, M.A., M.D. (U.S.A.)

"SYPHILITIC PHARYNGITIS."

To the Editor of THE LANCET.

SIR,—Your correspondent, "Med. Doc.," writes requesting suggestions for a special chronic syphilitic case in which all the usual remedies have failed. I would suggest the trial of succus alterans (McDade), prepared by Lilley and Co. There is much medical testimony in its favour, and the formula is given with the medicine. It would be interesting to report the result in THE LANCET.—I am, Sir, yours faithfully,

July 20th, 1886. H. G. S.

A SIGN OF DEATH.

AT a recent meeting of the Société Médicale d'Amiens, M. Lessenne mentioned the following as a simple and trustworthy sign of death. After pricking the skin with a needle the puncture remains open, just as when a piece of leather is pricked. On the living body, on the contrary, even if the blood does not come to the surface, as would happen if the person were hysterical, the pin-prick closes at once, and does not leave the slightest trace.

A General Practitioner.—The charges are reasonable, and, if the patient is so too, our correspondent should have no trouble.

OUR POLICE DRESS.

To the Editor of THE LANCET.

SIR,—I am glad you have called the attention of the public to the urgent necessity of providing a summer garment for our police. I am happy in reporting that in this county our defenders of life and property are enjoying the luxury of freedom from a Siberian costume which weakens the body and impedes respiration. For many years I have advocated this sanitary improvement, which has received the approval of medical authorities; and I am at a loss to understand why all the counties in England should not participate in the same privilege which has been conferred on the county of Somerset. I suppose the tyranny of routine blocks the way to reform. Rural "letter-carriers" equally deserve our sympathy, and they ought to be supplied with some "relief dress" when the thermometer stands, as it does this day, at 100° in the sun. Poor fellows! No wonder the farmers occasionally volunteer a drink of cider for these thirsty souls as they travel life's dusty journey; and if this draught could be supplemented with a trifle of bread and cheese it would be all the better for the "postal stomach." These sons of toil not only carry heavy bags of letters and newspapers, but are handicapped with parcel-post consignments, weighing from 10 lb. to 11 lb. of fish, flesh, and fowl. I know a rural post-carrier who walks, heavily laden, eighteen miles a day. At one time he was a well-to-do shoemaker, but boot and shoe machinery and competition took the bread out of his mouth. The dignity of labour is well illustrated in the daily life of this worthy disciple of St. Crispin. I wish he could look forward in his old age to a retiring pension. Hoping that this appeal will reach the authorities in Scotland Yard and the General Post Office,

I am, Sir, yours faithfully,

ARTHUR KINGLAKE,
Justice of the Peace for Somerset.

Haines Hill, Taunton, July 20th, 1886.

HYDATID DISEASE IN VICTORIA.

HYDATID DISEASE has so rapidly increased in Victoria that the Central Board of Health have issued a circular to all local boards pointing out the danger of drinking open natural waters to which dogs and other animals have access unless the water be first well boiled. The number of deaths from hydatid disease in Victoria during 1884 was fifty-nine.

"CIRCUMCISION UNDER THE INFLUENCE OF COCAINE."

To the Editor of THE LANCET.

SIR,—With reference to the interesting case of circumcision reported in your last issue as having been performed under the influence of cocaine by Dr. Atkinson, I beg to send you short notes from my case-book of two cases I operated upon last year with similar success.

CASE 1.—Jan. 13th, 1885. H. G——, aged nine. Sixteen minutes after injecting into the prepuce five minims of a 2 per cent. solution of cocaine in two places, and after smearing the prepuce all over twice with the solution, the operation was completed without the little patient suffering any pain.

CASE 2.—Feb. 12th, 1885. A. G——, aged four. The same steps were followed in this case, and an equal absence of pain during the operation was noted.

I have also performed the operation of removing a piece of skin from the lower lid for entropion with success, under the influence of cocaine, in an old woman aged sixty-seven. The same amount was injected as in the cases of circumcision, and the operation performed without causing any pain twenty minutes after the first injection.

It is well that such cases as the above should be from time to time reported in your valuable journal, as I feel convinced that the use of cocaine by the general practitioner is not so extended as is warranted by its well-authenticated anæsthetic properties.

I am, Sir, your obedient servant,

WM. THOS. JACKMAN, M.R.C.S., &c.

Coggeshall, Essex, July 17th, 1886.

PRINCIPALS AND ASSISTANTS.

L.R.C.P. & S. complains of the way in which he, as an assistant, was treated by his principal with regard to the mode of dismissal—viz., with only one week's notice. "L.R.C.P. & S." suggests that assistants upon engagement should make certain that a month's notice will be allowed before their services are dispensed with.

W. H. Munro, M.A., M.D. &c.—The gentleman referred to has no legal right to use the title mentioned on the strength of the qualifications named. But we hesitate to advise our correspondent to commence litigation. Law for almost anything is a doubtful remedy; for the use of false and misleading titles it is especially so.

ERRATA.—The latter clause of the last sentence but one in Dr. Morison's letter published last week, page 147, should read thus: "*In* others, anxious and quite possibly able to act efficiently, the tradition of his class, being unable to cope with difficult cases, withholds that public confidence," &c.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Poore, London; Dr. Steavenson, London; Dr. Aveling, London; Mr. E. D. Bower, Gloucester; Dr. McK. Johnston, Edinburgh; Mr. Vickers, London; Mr. Craig, Llandudno; Dr. Strain, Mexico; Messrs. Griffin and Co., London; Dr. J. H. M. Clinical Lectures
ON
CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE VII.

ON GASTRIC AND PERIGASTRIC ABSCESSES.

(*Concluded from page 112.*)

LET us now inquire into the state of health of the subjects of perigastric abscess previous to their final attack of illness. I have been able to collect the history of twenty-four cases as regards this point, and only two of the whole number are said to have previously enjoyed good health. But when the details of the post-mortem examinations of these cases are examined, it is evident that their histories must in this particular have been inaccurate; for in one the perforating ulcer is described as having "round and smooth edges," characters that would only be afforded by an ulcer of some duration; and in the other a cicatrix is described as existing opposite the perforation. With respect to the remaining twenty-two, the great length of time during which the symptoms of gastric ulcer had been experienced is very striking; thus, only two had complained of them for less than one year, eleven had been ill from one to four years, four for periods varying from eight to thirty years, and of five it is recorded "they had suffered for many years." In every case pain of the epigastrium or abdomen had been the chief subject of complaint, and in most there were also signs of dyspepsia; in seven vomiting was a prominent symptom, but in only two is there any mention of hæmatemesis. The absence of hæmorrhage is important, as confirming what we know from the histories of the cases, that the ulcers are usually of long duration; for this symptom is the result of an extension of the disease, and is rarely an accompaniment of an old indolent sore. The symptoms of course varied according to the part of the stomach which was the seat of the sore. For example, in the following rare case, which was admitted into the hospital under the care of Dr. Langdon Down, the ulceration had produced a narrowing of the lower end of the œsophagus, and the symptoms were those of stricture of this part.

CASE 6.—A female, aged forty-two, had been ill for nine months. At first she suffered from difficulty in swallowing, which gradually increased, and for the last two months she has been unable to take any animal food. "When she attempts to eat it retching comes on, but she has no pain except when eating." She was very weak and feeble, and had been losing flesh. Respiration much prolonged at each apex.

Post-mortem examination.—"The peritoneum was covered with recent lymph, and tubercles were scattered over the intestines and mesentery. The stomach was adherent to the left lobe of the liver, and when the adhesions were separated there was thick greenish matter like inspissated pus. The pyloric end of the stomach was not thickened, but there was an ulcer at the œsophageal end the size of a crown-piece, with indurated edges; the œsophageal end was pushed aside, indurated, and bounded by thick tough tissue, and the solid fibrous tissue which surrounded the œsophagus extended for one inch upwards. The upper fourth of the lungs was fibroid, and there were cavities the size of walnuts in them."

As both the lungs and the neighbourhood of the gastric ulcer in the above case were the seat of fibroid thickenings, it is probable that there was some common cause capable of producing it. There was no history of syphilis, but considering how often both the stomach and the lungs are affected by this disease, it is possible that it may have been the cause of the mischief in both. Ordinary tubercular affections are not a common accompaniment of perigastric abscess, for I have only been able to collect five cases in which they coexisted.

The final illness of which the patients affected with perigastric abscess died was usually ushered in by severe symptoms, and was of short duration. In seven out of twenty-three cases in which details are afforded, sudden collapse occurred, accompanied or followed, as soon as the collapse passed off, by pain of the abdomen or of the epigastrium, along with tenderness on pressure, distension, and other symptoms of peritonitis. In eleven there was no collapse, but the pain in the epigastrium is recorded as having suddenly become more severe. Rigors are mentioned only in three instances; in one as associated with collapse, and in the others as accompanying severe epigastric pain. Of the five cases in which the formation of the abscess was not ushered in by collapse or increased epigastric pain, one was suffering from phthisis and one from cancer, affording an example of what we have in a former lecture had to point out to you, that abdominal abscesses may occur in persons who are in a very feeble state of health, without any well-marked symptoms. The third case was admitted into hospital with symptoms of pneumothorax, arising from perforation of the diaphragm by the abscess; and you can easily understand how in such a condition the patient may have been unable to afford any distinct history of her former state of health, and consequently the symptoms indicating the formation of an abscess may not have been recorded. In another the first symptoms were severe constipation and vomiting; and the fifth case had for a length of time been affected with an abdominal tumour which suddenly burst into the stomach, and was rapidly followed by fatal exhaustion.

We are justified, then, I think, in concluding that in every case of perigastric abscess, excepting where it occurs in persons affected with phthisis, cancer, or some other chronic exhausting malady, the first formation of the abscess will be accompanied either by collapse and signs of general peritonitis, or by sudden and severe pain of the epigastrium, attended with indications of local peritonitis.

The absence of repeated rigors is worthy of remark, as it may often enable you to exclude this condition where the diagnosis is doubtful. A patient, for example, is at present in my wards who was admitted with severe rigors repeated daily, as in ague. This and the absence of any history of gastric or duodenal ulceration enabled us to exclude local peritonitis; and as he has been for three or four weeks expectorating lung tissue, and there are signs of consolidation at the base of the lung, it is probable, as was at first conjectured, that an abscess in or near the liver has perforated the diaphragm.

On inquiring into the course of perigastric abscess, it will be advisable to separate such as commenced with symptoms of collapse from those in which this was not present. Looking, then, at the collapsed cases, we find that in one instance this condition persisted until death, which took place in twenty-two hours; but it was found on post-mortem examination that the abscess had been present for some time and had burst into the peritoneal cavity. In the others the collapse gradually decreased, and the patient chiefly complained of severe and continuous pain in the abdomen or epigastrium, with tenderness on pressure, distension, and fever. Vomiting was a prominent symptom in one case and diarrhœa in another. In five perforation either of the pleura or pericardium occurred, and in two the patient complained of a sensation as if something had suddenly given way. In five cases in which the duration of life is given, the average of the last illness was thirty days. Details are afforded in nine cases where collapse was not present, and in all severe and continuous pain in the abdomen or epigastrium persisted until death, attended with tenderness on pressure; but there is no record, as we should have expected, of constant vomiting. In one pus was vomited, but there is no notice of hæmatemesis. In five pleurisy was set up; in four of these by perforation of the diaphragm. The average duration of life was less than in the collapsed cases: four died within two weeks, and two lived more than a month after the commencement of the fatal illness. Fever is mentioned in nearly all as a prominent symptom, but I have been able to find only one or two in which the course of the temperature is noted.

Occasionally temporary recovery ensues after the formation of the abscess, and instances are recorded where the patient was able to return to his employment, and was afterwards attacked with general peritonitis arising from rupture of the sac. We may suppose that in such instances the pus had become walled in by fibroid tissue, as in the following, which was admitted into this hospital under the care of Dr. Hughlings Jackson.

CASE 7.—Male, aged fifty-one. "He met with an accident two years ago, and then vomited blood. He has since suffered from pain of the stomach, not increased by food. For the last week he has suffered constant pain; the abdomen is distended; has had nausea, but no vomiting. The pain is increased by the act of breathing." The next day he is mentioned "as lying on his back and as moving very cautiously; the pain was chiefly in the epigastrium, but he shrieked out directly the abdomen was touched. The lower part of the chest and of the abdomen were quite hard and rigid." On the following day there was noticed a friction sound at the left base.

Post-mortem examination.—"A chronic ulcer of the stomach along the lesser curvature, nearer to the œsophageal end, which had perforated all the coats. Old perforations and adhesion of the stomach to the liver, and an abscess was situated a little above the ulcer. The stomach was firmly adherent to the under surface of the liver, and there was thickening between the left lobe of the liver and the œsophageal end of the stomach and diaphragm. On separating the stomach some pus escaped, and a cavity was opened, bounded above by the diaphragm, on the left by the diaphragm and spleen, on the outer side by the left lobe of the liver, and below by the stomach; so that the abscess was situated chiefly between the diaphragm and the stomach. It was surrounded by fibroid tissue, showing that it had existed for some months. The cavity was about an inch from the floor of the ulcer, being separated from it by fibroid tissue."

It will be observed that the patient complained of pain increased by breathing, and we can readily understand how such would be the case, as the abscess was in immediate contact with the diaphragm. I have not found this symptom noticed as a prominent one in the other histories I have collected, but it is probably not uncommon. In many of those in which perforation into the pleura is mentioned we have unfortunately very scanty details of the symptoms; but in those that are more carefully recorded the patients were suddenly attacked with severe pain of the side and urgent dyspnœa. In one rigors are said to have preceded the chest symptoms, as in Case 2; in another the patient became rapidly unconscious; one complained of a sensation as of "something had given way"; and in all the sudden pain was quickly followed by fever. In one only the pleurisy was accompanied by jaundice, but no light was thrown by the post-mortem examination on the cause of this condition. Where the abscess opened into the pericardium still more striking symptoms were produced. One complained of a feeling "as if something had burst," and all experienced severe pain in the heart's region, accompanied by great dyspnœa; the pulse was very small and rapid, the extremities cold, the patients extremely restless, and death occurred on the third or fourth day after the accident.

Such are the usual symptoms observed in cases of epigastric abscess, but occasionally the ordinary difficulties of diagnosis inseparable from such an obscure disease are increased by the coexistence of some other disorder. For example, a case was admitted under Dr. Sansom in which, on post-mortem examination, the following conditions were discovered:—

CASE 8.—"General peritonitis, dilated stomach, and stricture of the pylorus; a large ulcer with sharp edges and a perforation in the centre of its base, and a large cavity between the walls of the stomach and the liver surrounded by organised lymph. There was also a large aneurysm of the abdominal aorta eroding three of the vertebræ, and also fibroid thickening and consolidation at both apices." Unfortunately, the history of this case is lost, but you can readily imagine what a complicated clinical picture it must have presented to the physician, and how impossible it would be to diagnose the state of so many important organs simultaneously affected.

You will observe that there is nothing very distinctive in the symptoms of perigastric abscess, but we shall find that in many instances the physical signs are very characteristic. When we examined the subject of duodenal abscesses, we deferred the consideration of the physical signs accompanying them on account of their similarity with those of perigastric abscesses; and in the remarks I now propose to lay before you I shall include abscesses connected with both of these sections of the digestive tract. In a small number of cases, as has been before mentioned, no communication could be discovered between the ulcer and the abscess, although there was no doubt that the latter was the result of the irritation set up internally. The physical signs in such cases are, of course, somewhat different from those we have before mentioned, as the contents of the abscess consist of fluid only, and gas and liquid do not coexist, as in those that communicate with the interior of the digestive canal.

A tumour capable of being distinguished externally is mentioned in only six of the cases arising from ulceration of the stomach; but it was almost always present where the disease was associated with cancer. The rarity of a tumour in the former class is easily explicable when we remember that in most instances the pus lies very deeply, and is in relation with the diaphragm. But there is, I think, another reason which may account for its being so rarely recorded, and that is the very tense state of the muscles, especially mentioned in Case 2, that almost always accompanies any painful condition of the upper part of the abdominal cavity, rendering its exploration exceedingly difficult. Whenever a tumour was present it was very tender; but in one instance it is stated that slight pressure produced no complaint, whilst deep pressure caused considerable suffering. In each instance the tumour at first felt hard, but this was soon replaced by the sense of fluctuation.

In most the percussion note was at first dull, but afterwards tympanitic, and in all probability this took place on account of the tumour becoming more superficial. In one well-reported instance the sound was at first dull, afterwards tympanitic, then lessened in bulk after an attack of diarrhœa, and finally disappeared, the contents of the abscess having been discharged through the diaphragm. In another the line of dulness varied according to the position of the patient, showing that the cavity was of considerable size, and that it contained both air and liquid. One reporter mentions what is an important sign in the diagnosis of these tumours—viz., that it was immovable both on full inspiration and by external pressure.

There are other signs which will assist you to ascertain the presence of a tumour situated below the diaphragm, whether its contents are only fluid or also contain air. Thus the affected side may be enlarged more than the opposite one, a point which can be determined by measurement or by the eye. Generally the lower ribs are thrown outwards, so that the angle formed by the edge of the hypochondrium and a line drawn from the ensiform cartilage to the umbilicus is larger than that of the opposite side. In a small number of cases the pus was in contact with the ribs, and where such is the case one or more of the intercostal spaces may be discovered to be unusually wide. You have seen lately two instances in which the diagnosis of a hydatid tumour was determined by means of such observations. In each there was no decided epigastric tumour and no bulging in the upper line of the hepatic dulness, but the lower ribs on the right were higher than those of the left side, while the hypochondriac angle and the breadth of one of the intercostal spaces were increased. In each case a deep exploratory puncture was made between the ribs, and the cyst was successfully emptied. When there is a collection of pus situated just below the diaphragm the organs below it are of course depressed. In one instance a tumour was discovered in the region of the spleen, as in Case 2; in another the lower edge of the liver extended a considerable distance below the hypochondrium. This displacement would be a most valuable indication of all subphrenic tumours, were it not, as has been before stated, that the abdominal muscles are usually in such a state of tension that the necessary examination is attended with great difficulty. It is important to bear in mind that the change in the position of the heart is either very slight, or the organ is only tilted upwards by the fluid beneath it. In pleuritic effusion, as you are aware, it is pushed towards the opposite side, but in subphrenic abscess this does not occur. In all cases, unless the abscess is of very small size, the diaphragm is thrust upwards, and the lower lobes of the lung are compressed; consequently, there is dulness on percussion, which is more evident behind than in front. You can distinguish this from a collection of fluid, as the tactile fremitus is increased, and is accompanied by diminished respiration and generally by fine crepitation. In most of the reports the dulness is said to have reached as high as the angle of the scapula, and the line of dulness in front is also stated to have been higher than in the normal condition. I have not met with any remark as to the line of dulness being curved, as is not unfrequently the case in hydatid and other cysts of the

liver; but this probably arises from the fact that the dulness is the result of the compression of the lung alone, the abscess being more deeply situated than in the case of hepatic cysts.

You must bear in mind that an abscess in connexion with the stomach generally contains both air and liquid, and is therefore in a similar state to a pleura which is the seat of pneumothorax; consequently the sounds, such as amphoric respiration, metallic tinkling, and splashing on succussion, which are usually looked upon as characteristics of the latter, may also present themselves in the former condition. This was first pointed out in a case published by Dr. Barlow and Dr. Wilks as far back as the year 1845, and these observations have been since confirmed by many other observers. The amphoric sounds are, however, generally not confined to the thorax, but can be often heard over the whole abdomen, and, in some instances are audible to the lower border of the spine.

There are no special physical signs when the abscess bursts into the pleural cavity. If it has contained air, the ordinary evidences of pneumothorax present themselves; but if only fluid, then the signs of pleuritic effusion can be

FIG. 2.

recognised. In one instance, when the chest had been aspirated, the fluid removed was found, on microscopical examination, to contain particles of food, proving of course that the mischief had originated in the digestive canal. Where the abscess opens into a lung previously adherent to the diaphragm, pneumonia is set up, and you may find by microscopical examination particles of lung-structure in the sputa. In the rare cases where a perigastric abscess has burst into the pericardium, physical signs of great interest have been remarked. The pericardium, being distended with air, presented a clear note on percussion, instead of the normal dulness, whilst the motions of the heart were accompanied by a metallic sound, which in some cases was loud enough to be heard by the side of the patient's bed.

As you may readily imagine, there is often great difficulty in the diagnosis of perigastric abscess, and you are liable to confound it with a number of tumours situated in the upper part of the abdomen. You will frequently see in the wards hydatid cysts presenting themselves in the left hypochondriac region, and when they suppurate you may easily mistake a perigastric abscess for one of those tumours. But the history of a hydatid is very characteristic; it is often discovered by accident, and has generally been for a considerable length of time unattended by pain or any other inconvenience excepting such as may arise from its bulk, there has been no previous emaciation or deterioration of the general health, no pain after food or vomiting. A hydatid tumour is always dull on percussion, is not lessened by diarrhœa or vomiting, can be generally shown by careful manipulation to be in connexion with the liver, and, unless adhesions have been extensively formed, it moves with the respiration or by pressure. You are more likely to mistake a perigastric abscess for a hepatic abscess, unless you bear in mind that the latter almost always arises from dysentery or an affection of one of the abdominal organs whose circulation is connected with the portal system. It chiefly occurs in persons who have lived in the tropics, and have been previously healthy; its course is acute, is usually attended with repeated rigors; the tumour is quite dull on percussion, is never tympanitic, and is never accompanied by signs of pneumothorax. As has been already pointed out, in some of the cases of perigastric abscess the signs of pneumothorax have been observed where there has been no perforation of the diaphragm, and consequently a mistake in diagnosis has often been the result. Forty years ago two

FIG. 3.

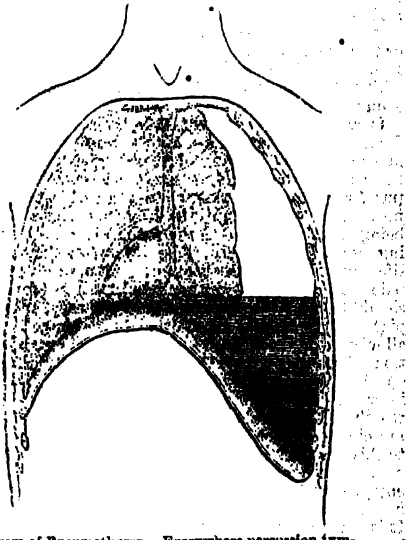

Diagram of Pneumothorax. Everywhere percussion tympanitic; movements of chest, inspiration, tactile fremitus, and vocal fremitus diminished or absent; amphoric sounds; heart displaced.

cases of this kind were correctly diagnosed by Dr. Barlow, and of late the characters distinguishing these conditions have been clearly pointed out by Dr. Leyden. In pneumothorax there is usually a history of cough, dyspnœa, hæmoptysis, or other signs of pulmonary disease; whilst in perigastric abscess the patient has previously complained of pain after food, dyspepsia, or other symptoms pointing to disorder of the digestion. In the former the whole of the affected side is enlarged, the intercostal spaces are flattened, and the movements of the chest are everywhere absent; whilst in the latter only the lower part of the chest is distended, and the upper portion of the affected side moves in breathing. In pneumothorax there is an absence of the respiratory murmur and of the tactile fremitus all over the affected side; whilst in perigastric abscess the respiratory murmur can be heard for some distance down the side, and is audible at a lower point in forced respiration than in ordinary breathing. In addition to this, the amphoric sounds are often audible over the whole abdomen and even to the bottom of the spine in perigastric abscess, instead of being confined to the immediate neighbourhood of the thorax; the heart is generally pushed to the opposite side in pneumothorax, but is only tilted upwards in the case of perigastric abscess. The accompanying diagrams (Figs. 2 and 3) will make these distinctions more plain to you than mere verbal descriptions.

There is another very rare condition which in some respects resembles perigastric abscess and might lead to a doubt in diagnosis. In diaphragmatic hernia portions of the abdominal viscera find their way into the pleura, which is almost always the left, and you will remember it is also the left side which is commonly affected in perigastric abscess. As the pleura contains organs filled partially or wholly with air, there is also in such cases a tympanitic note over the lower part of the chest, and often a metallic sound when the stethoscope is applied to the part whilst percussion is made near it with the pleximeter. The various amphoric sounds are also audible, as in the case of pneumothorax and of perigastric abscess, where there is a communication between the abscess and the stomach. There are, however, well-marked points of difference between these conditions. Perigastric abscess is preceded by symptoms of ulceration of the stomach; diaphragmatic hernia is mostly the result of injuries, although in some instances it is congenital. The former is always accompanied by severe pain, tenderness of the part and fever; the latter, unless strangulation has taken place, may be without any symptoms, or these may be only temporary—such as dyspnœa directly after food, evidently dependent on the pressure of a distended stomach. In perigastric abscess the heart is tilted upwards, and the abdomen is tense, tender, and prominent; in diaphragmatic hernia the heart is pushed to one side, and the upper portion of the abdomen is flattened or retracted. In the former the physical signs often vary from day to day; but in the latter they frequently alter, even whilst the patient is under examination, and especially as soon as he has taken food or drink.

It will be quite evident that, as perigastric and peri-duodenal abscesses are usually the result of ulceration commencing in the interior of these organs and perforating their coats, we are powerless to prevent the formation of pus by medical treatment. In the early stages we must insist upon perfect rest, the least movement of the body being strictly prohibited; the withdrawal of all food, excepting what is absolutely necessary for the maintenance of life; and the administration of opium, in order to relieve pain and prevent vomiting. In most cases the patient should be fed by means of nutrient enemata, and only small pieces of ice should be allowed to be sucked in order to alleviate thirst. When we have clear evidence of the formation of an abscess, the treatment can only be surgical, an opening being made into the abscess and a drainage-tube inserted. But the question will naturally occur to you whether a favourable issue to such a case can be fairly anticipated if such measures should be adopted. In answer to this question, let me remind you of the number of cases on record in which patients have survived, and, in fact, enjoyed good health, after a communication had taken place between the stomach and the external surface of the body. It is true that in many of these adhesions had been formed between the stomach and the abdominal parietes, but in others it is distinctly stated that an abscess was first discovered in the abdomen, which subsequently burst externally. Cases, again, are on record in which the contents of the abscess seem to have been evacuated through the digestive canal, and the patient recovered. The following very interesting and instructive example is recorded by Dr. Hilton Fagge.

CASE 9.—A man, aged thirty-seven, who had always enjoyed good health, nine months before his admission into Guy's Hospital was kicked by a man on the left side. A swelling formed there, and gradually increased in size. Twelve days after his admission he vomited a small quantity of blood, which recurred next day. The tumour is described "as a rounded mass extending deeply, so that no lower edge to it can be felt. Its inner border reaches the middle line of the body, and it reaches downward to within an inch of the umbilicus. It is perfectly dull except along its inner border. Here there is a tympanitic resonance, less clear, however, than over the adjacent stomach. The heart's impulse cannot be felt below the nipple at all. It is felt above the nipple between the third and fourth ribs, and also above the third rib. On listening to the heart's sounds in this position, they are perfectly natural; but below the nipple very curious gurgling sounds are audible, synchronous with the heart's beats. They are of a metallic or musical quality, the systole being often accompanied by several distinct tinkling sounds." At a subsequent date it is recorded that "the gurgling sounds can now be heard without the aid of the stethoscope, and even at the distance of three feet from the patient, but they are not constant. There is now tympanitic resonance over the tumour, except when he lies on his left side; this causes the disappearance of the tympanitic percussion note." He was discharged from the hospital at his own request, "but he came back some time afterwards, and said that the tumour had suddenly disappeared, having discharged a quantity of matter which I suppose he must have vomited, although there is no note of the fact in the report. On examination it was found that he was right in stating the tumour was no longer to be discovered. The man appeared to be quite well."

Now, although the foregoing case differs from most of those we have before examined, inasmuch as the abscess would seem to have commenced externally to the stomach and to have been the result of an injury, yet the vomiting of blood, the well-marked physical signs, and the eventual disappearance of the tumour after a discharge of pus, seem to prove that there was a communication between the abscess and the stomach, and if so, that cases of perigastric abscess may terminate favourably. But you will remember that in a large proportion of cases perforation of the diaphragm takes place, and pneumothorax or acute pleurisy is set up before the existence of the abscess can be clearly made out. Does this condition, then, admit of recovery? Let me quote you a case of Dr. Tilmann's bearing upon this question.

CASE 10.—The patient was a boy, previously in good health, who, after an apparently slight injury, complained of pain in the region of the liver. On the third day the pulse became rapid, the temperature rose, there was no vomiting, but the bowels had not acted for three days, and the hypochondrium was tender. The bowels were opened by an aperient; but on the eighth day there was some exudation into the right pleura, with a tympanitic percussion note in one part of the chest. On the fourteenth day, after a full meal, the patient was attacked with severe pain of the right side, and there was a dull note on percussion all over that side, with the exception of a space in the upper part, where the note was tympanitic. The chest was aspirated, and a fluid resembling a fine emulsion of fat was removed, containing small patches of starch. A drainage-tube was inserted, and subsequently particles of food were discovered in the fluid evacuated through it. Notwithstanding this, the patient gradually recovered, and was dismissed cured six months after the onset of the illness.

The commencement of the illness in the above case immediately after the receipt of a trifling injury was probably only accidental, and the patient had most likely previously had an ulceration of the duodenum. The presence of air, however, in the pleura and the withdrawal from it of fluid containing particles of food prove that there was a communication between the cavity of the chest and some part of the digestive canal. But this case also shows conclusively that treatment may be successfully adopted even in circumstances that appear to be most unfavourable, and that a communication with the interior of the digestive tube does not necessarily prevent a favourable result following surgical interference.

ABSTRACTS OF

Lectures

ON

RHEUMATISM IN CHILDREN.

Delivered at the Hospital for Sick Children, Great Ormond-street.

BY ANGEL MONEY, M.D., M.R.C.P.

THE lecturer opined that it was legitimate to speak of a children's type of rheumatism. A typical case of rheumatism in a child might be pictured as one that presented in the course of a single attack of the malady the following phenomena: erythemata, nodules of the subcutaneous variety, now so well known, joint affection, endocarditis, and chorea. Dr. Money said that he had seen all these phenomena occur in the course of a single attack of rheumatism in a child. Briefly put, the children's rheumatism might be said to be characterised by the frequency of occurrence of erythemata, nodules, endocarditis, and chorea, and by the slightness of the arthritis and pain, pyrexia and

sweating. He also advanced the view that arthritis was even of very doubtful occurrence, and considered that the slight effusions about joints met with in the rheumatism of children ought to be regarded as of the nature of a periarthritis, the slight spontaneous pain and not great tenderness certainly not militating against such a view. He was of Dr. T. Barlow's opinion, that effusion into the sheaths of tendons was decidedly a feature of the rheumatism of children. The subcutaneous nodules were regarded as of the first importance in the study of the affection in childhood. Accepting Dr. Barlow's homology between them and the bases of valvular vegetations, he thought we might consider that the changes in the one were in some sense representative of the alterations in the other. It was reasonable to suppose that, so long as the nodules came and went, similar alterations might be taking place in the valvular lesions. He still adhered to his opinion expressed three years ago, that in half the cases of severe rheumatic heart disease in children nodules might be found. The greater frequency of endocarditis in children might be partially accounted for by the slight painfulness of the arthritic manifestations, which did not prevent children suffering from a moderate degree of rheumatism from running about; mechanical strain probably thus played an important part in exciting the "nodular" valvulitis. It was by no means rare to find disease of the valves of the right side of the heart in rheumatic children. In rheumatism, chorea must be regarded, like the nodules, as a symptom, an expression of the disease. Although chorea, that attracted attention, was by no means a universal symptom of rheumatism in children, still it was remarkable, Dr. Money said, in his experience, how very frequently a slight amount of involuntary twitching of the fingers was present. Erythemata were probably even more frequently present than observed, for they were sometimes so fugacious as to be easily missed. Stiff-neck and back-ache were probably affections of the interstitial connective tissue of muscle, and not an affection of the muscular protoplasm proper. He had seen rheumatic nodules develop around a joint which at the time showed decided signs of effusion of the kind usually seen in children.

If we contemplated the course of the various rheumatic phenomena, it would be observed that they all tended to come and go, and in this respect they exhibited a series of degrees of duration beginning with erythemata, which were the least durable, passing on to periarthritis, teno-synovitis, nodules, chorea, and endocarditis. Doubtless, no absolute rule could be laid down in this regard, but the comparison was worthy of entertainment. Was there a single essential lesion in rheumatism? Might we look upon the various rheumatic phenomena as of equivalent order? The cause of rheumatism, whatever it might be, was liable to produce slight localised inflammations, having a remarkable tendency to subside. It was possible that an erythema might be regarded as the essential semeiological rheumatic element. In the skin such a lesion could easily pass away; in subcutaneous tissues its effects might be more marked and more lasting, though still tending to disappear; so with the heart. Could we regard the chorea of rheumatism as the result of multiple erythemata of some part of the motor apparatus of the brain and spinal cord? It was curious that so many of the rheumatic lesions had been ascribed to embolism; it would be easy enough to regard the papular and marginal forms of erythema as due to trifling multiple embolism, just as the purpura had been so explained; likewise the migratory joint affection, as Hueter held; and why not the nodules as well as the chorea? But embolism could hardly explain the nodular valvulitis or beading of valves; nor probably the tendency that sometimes existed for pericarditis to assume a nodular form, as both Dr. Barlow and Dr. Money had actually found at the necropsy of cases of rheumatic disease in children.

In conclusion, Dr. Money considered that the rheumatism of children was one of the most hopeful affections that the medical man could have to treat, provided that the diagnosis be made at an early stage of its development—a very large proviso. But the affection might be easily overlooked on account of the slightness of the subjective symptoms. How important was it that a most careful physical examination should be made in all cases of even slight ailments! Some of the rheumatism of children was so insidious in its operation, that it was conceivable for the disease to be at work without giving signs either of a subjective or an objective order.

A child who has any sign of rheumatism about it should be kept absolutely all day and night in bed. Even if a mere urticaria or erythema be the only sign to be found, the bed should be tried for a day or two and the case watched for other members of the rheumatic series. Whilst holding that erythemata, the nodules, periarthritis, chorea, and heart disease were perhaps most frequently of rheumatic origin in children, Dr. Money allowed fully that any of these symptoms might own several other causes. Not all erythemata and chorea are rheumatic, nor is all periarthritis and endocarditis of rheumatic origin.

The severity of rheumatism in children may be measured by the appearance and clinical development of the nodules. The nodules, both of the subcutaneous tissue and the valves of the heart, are a guide to the degree of rheumatism and to its character. Some kinds of rheumatism resemble the shocks of the interrupted current, and others have more of the continuous character, smouldering in its manner. Dr. Money had seen abundant crops of nodules with signs of genuine heart disease come with the suddenness of a flight of birds, and disappear almost in the same rapid but in a more straggling manner; and these severe attacks may be repeated, leaving the patient somewhat devitalised, yet with prospects of a complete restoration to health. It was quite another thing in the rheumatism that was less intense but more continuous; this was the variety which Dr. Money believed led to further fibrotic changes in the valves, and sometimes in cases of this slowly progressive course the nodules abated some of their tendency to disappear, and remained for weeks and months together. No doubt intermediate stages between these two forms existed.

As to the further treatment of rheumatism, the principles were of the simplest order, but at the bedside many details had to be borne in mind and must be acquired by the practitioner himself, for no amount of lecturing could impart the necessities of treatment of any individual case. Dr. Money had faith in the employment of moderate quantities of bland fluids like barley-water or toast-and-water, to which might be added the alkaline carbonates, the effects of which were probably, he suggested, enhanced by their administration in dilute form. Salicylate of soda or salicine was of value in some cases of rheumatism in children, but in his experience of less value than in adults, whose pain and joint affection were so much more a part of their suffering.

Some of the most disheartening cases that could fall to the lot of the medical practitioner were those which presented a picture of pallid cachexia simulating the appearance of a neglected case of empyema. Here the child may be breathing rapidly, with a dry skin and clubbed fingers; with severe heart disease manifested in the rapid heaving action, loud murmurs, and thrills; with bronchitis, worse in the left lung, and even with patches of pleurisy about the bases of the lungs and elsewhere; with nodules about the ankles and elbows, considerable emaciation, and an almost undiscoverable effusion about two or three joints; and yet with a temperature that does not transcend 101° in the course of the twenty-four hours, and which may for a greater part of the time be not above 99° or even the normal.

NOTES OF A CASE OF EXCISION OF THE LARYNX FOR MALIGNANT DISEASE.

BY DAVID NEWMAN, M.D.,

SURGEON IN CHARGE OF THE DEPARTMENT FOR DISEASES OF THE THROAT AND NOSE AT THE ROYAL INFIRMARY, GLASGOW.

THE following is a short report of one of the few successful cases of extirpation of the larynx for carcinomatous disease. It is not possible, even although six months have elapsed since the operation, to state positively that the patient has been cured of his disease; but I think the fact that there is not the least evidence of recurrence, and the circumstance that the patient is rapidly gaining in weight and is now able to follow his occupation, afford us some reason to believe that his chances of complete cure are considerable. The points in his favour are that the disease was strictly limited to the laryngeal cavity, and the fact that not only the epithelioma, but along with it a considerable portion of healthy tissue, was removed, reduces the tendency to recurrence to a minimum.

I believe that the high mortality in complete laryngec-

tomy has arisen from the fact that the cases have not been carefully selected, and the operation has been performed without sufficient regard to the circumstance whether or not the growth was limited to the cavity of the larynx. For extrinsic carcinomatous disease laryngectomy seems to me unjustifiable, for two reasons—the immediate dangers of the operation are great when not only the larynx but also large masses of glands or portions of neighbouring organs require to be removed, and the possibility of eradicating the disease is extremely small. But while I willingly admit that growths of a cancerous nature, originating in the larynx and spreading beyond it, are not suitable for extirpation for the reasons I have just stated, I do not see why intrinsic carcinomata which have not yet exhibited any evidence of glandular involvement should not be removed with a good prospect of saving the patient.

Laryngeal carcinomata are, as a rule, intrinsic for a lengthened period, and therefore the time during which the operation may be performed with advantage is considerable; but, notwithstanding, it is of the utmost importance that, if the operation is to be performed at all, it should be undertaken as soon as the disease has been recognised, and probably the most certain way of clearing up a doubtful diagnosis is to remove a small portion of the growth by the endo-laryngeal method for microscopic examination. Such a simple operation is practically devoid of danger: if the neoplasm proves to be benign, the operation is but a step for its complete removal; if the growth is malignant, the sooner the fact is ascertained the better. I look forward to the time when very few cases of intrinsic cancer of the larynx will be permitted to involve the lymphatic system without an attempt being made to remove the primary growth.

The patient, J. W——, aged thirty-seven, was admitted into the ward for diseases of the throat and nose, Royal Infirmary, on Jan. 5th, 1886, and tracheotomy was performed on the 14th of that month. The following is the history of the case, as recorded in the ward journal:—About three years ago the patient first noticed a slight hoarseness in speaking, unaccompanied by pain or by any difficulty in swallowing or breathing. The hoarseness commenced about November, 1882, and continued until the following summer, when some improvement took place, but he was not certain whether the voice regained its former condition or not. The following winter (1883-84) his throat again troubled him, became worse than during the preceding year, and since then the disease has gradually developed to the present condition. He now complained of pain over the larynx, extending upwards to the left ear, but not increased by palpation. Aphonia was complete, and there was slight difficulty in deglutition. Digital examination externally did not reveal any alteration in size or form of the larynx, or enlargement of the lymphatic glands. The epiglottis was practically normal, but the aryteno-epiglottidean folds were thickened slightly, and the mucous membrane of the upper part of the larynx was hyperæmic. On the left side, midway between the arytenoid cartilages and the thyroid attachment of the false cords, there was a deep ulcer with a sharply-defined edge anteriorly, but posteriorly the edge was rounded, and the mucous membrane covering it presented a warty appearance. On the right side the mucous membrane was considerably thickened over the false cords; the true vocal cords were completely destroyed by a large ulcer, which extended down as far as the lower margin of the thyroid cartilage, and presented the characteristic appearance of an advancing epithelioma.

Tracheotomy was performed, as I have stated, on Jan. 14th, and on Feb. 1st I made the following note:—The patient stated that for the last few days the pain in deglutition had so increased that he had considerable discomfort in swallowing solid food. For some time back (two months) he had had difficulty in swallowing fluid food, but till lately he had been able to swallow solids without pain or even uneasiness. This change was accounted for by the fact that within the last week the mucous membrane covering the arytenoid cartilages and the inter-arytenoid fold had become considerably indurated, apparently by inflammatory products. The only other change worthy of note was an increase of pain over the larynx and in the left ear. Previously to operating, I asked Dr. Perry to examine the patient, especially as regards the condition of his heart and lungs. These Dr. Perry pronounced as practically normal. Having satisfied myself, by microscopic examination of a portion of it, that the growth was an epithelioma, I asked Drs. Macewen and Knox to assist me in the operation.

In excising the larynx, I made a median incision from the lower edge of the hyoid bone to the tracheotomy wound, which was situated on a level with the second ring of the trachea. The skin and subcutaneous tissues were then dissected from the thyroid cartilage in front, the anterior margin of the thyro-hyoid muscle was exposed, and the substance of the muscle was separated from the upper part of the cartilage by the handle of the knife, while the origin of the muscle from the oblique line on the side of the thyroid cartilage was separated by incision as far back as the pharynx. This was done first on the left, then on the right side. The other muscles—namely, the sterno-thyroid and the inferior constrictors—were then dissected, the edge of the knife being kept close upon the cartilage. The cricoid cartilage was then dissected out and the upper ring of the trachea exposed. When this had been done, the trachea was drawn forwards and upwards, and divided below the first ring. Up to this stage of the operation chloroform had been administered through the tracheotomy tube; but now that the trachea was divided transversely it was necessary to introduce a large-sized tracheal tube (Macewen's), with an indiarubber ring round the end in the trachea, in order to prevent blood from flowing into the air-passages, and also to permit chloroform to be administered at a little distance from the operator. The mucous membrane on the posterior wall of the trachea was then carefully dissected from the œsophagus; the superior cornu and upper part of the left ala of the thyroid were then cut through and separated from the rest of the cartilage, so as to permit the posterior part of the larynx to be more readily dissected from the pharynx. The thyro-hyoid membrane was then divided in front, the epiglottis was divided at its base, and the upper attachments of the larynx were cut through. A small portion of the mucous membrane of the pharynx was taken away along with the arytenoid cartilages. The portion of cartilage which was separated from the thyroid was then removed. All bleeding points having been secured, the trachea was stitched to the lower edge of the wound, and a large-sized tracheotomy tube was fixed in position. The wound was dressed with absorbent cotton-wool sprinkled with iodoform and enclosed in a casement of perforated green silk protective. The patient was then placed in bed, and no food was administered until the evening, when a feeding-tube was introduced into the œsophagus through the upper part of the wound, and retained in position by a piece of sticking-plaster.

In performing this operation, I divided the trachea and removed the larynx from below upwards. Some surgeons, however, prefer to do it in the opposite direction; this is a more tedious method, but it avoids the risk of blood entering the air-passages, on account of the severance of the larynx from the trachea being the last step in the procedure. These advantages are, however, counterbalanced in the method which I adopted by the circumstance that the operation can be performed more rapidly; while, by using a flexible gum-elastic tracheal tube, of sufficient size to fill the trachea, not only can the escape of blood into the lower air-passages be prevented, but the anæsthetic and the hands of the administrator are removed some distance from the field of operation. One point to which I desire to direct attention is the advantage of dividing the thyroid cartilage close to its upper posterior angle. By separating the superior cornu before dissecting the larynx from the œsophagus the operation is greatly facilitated, and the danger of injuring the œsophageal wall or large arteries is removed. Some operators ligature the superior and inferior thyroid arteries, and if necessary the superior laryngeal, or even the hyoid branch of the lingual artery, as a preliminary to the operation of extirpation; but, as far as my experience goes in laryngectomies, the hæmorrhage is by no means great, and can easily be controlled.

During the first few days after the operation the only food administered to the patient was milk, and this was supplied at the rate of three or four pints in the twenty-four hours. When the wound became firm, an artificial phonatory apparatus (Dr. Irvine's modification of Gussenbauer's artificial larynx) was introduced, and the edges of the wound were drawn over the upper or pharyngeal limb by strips of sticking-plaster. The phonatory apparatus was kindly made for me by Dr. J. Cowan Woodburn. The patient has now (July 20th, 1886) been wearing it for more than four months. His articulation is wonderfully good, and, except for its monotony, is not distinguishable from his

natural voice. The vowels are pronounced with perfect clearness, both when he speaks in a whisper with the reed out or when he attempts phonation. The reed remains silent during ordinary expiration and inspiration, but when the patient makes a slight effort the reed is thrown into vibration, and a pure note is produced which becomes modified in the buccal cavity into articulate speech. He is able to swallow both solid and fluid food without difficulty. On laryngoscopic examination all the parts are found to be perfectly normal and free from inflammatory changes, and the patient is able to follow his regular occupation (that of a confectioner) without inconvenience.

ON

NEURORHEUMA, OR NERVOUS ENERGY.

By W. HALE WHITE, M.D.,
ASSISTANT-PHYSICIAN TO GUY'S HOSPITAL.

WHEN light falls on the retina, or sound on that part of the ear which contains the terminations of the auditory nerves, or heat upon the sensory to heat nerve terminations, or electricity or a blow is applied to the termination of a sensory nerve, a sensation is transmitted to the brain along nerves going to that organ from the various peripheral terminations—as the retina. This may be proved by the simple experiment of cutting the nerve, when it will be found that no sensation reaches the brain on stimulation of the periphery of the nerve—i.e., if the optic nerve be cut, no amount of light falling on the eye will ever make us conscious of light. That something is transmitted along the nerves in each case there can be no manner of doubt. What it is, and how it is transmitted, we know no more than we know of the mode of transmission of electricity along a wire. It may be a vibratory motion, or it may be a fluid flow—that is to say, something emitted from one end of a nerve and transmitted along it to the other; these two views corresponding to the vibratory and emission theories of light. Or it may be that each molecule undergoes some chemical or other change which sets up a similar change in the molecule next to it, and thus the change is transmitted along the nerve. Or, lastly, the mode of transmission may be of such a nature that, with our present mental capacities, we are incapable of appreciating it.

But the fact that we do not know what it is that passes, or how it passes, need not prevent our having a word to express that something passes; as it is at present, we are content with such phrases as nervous current, nervous flow, nervous transmission, nervous energy. It would, however, be thought very cumbersome if, because, in the case of electricity, that particular form of energy is generally found flowing along lines, we were to talk of the wiry flow, the wiry current, wiry transmission, wiry energy. Would it not be better to have some distinctive word for that form of energy which flows along nerves and is stored up in nerve cells? As good a word as any is, I think, "neurorheuma" (that which flows along a nerve), and the derived adjective would be "neurorheumal." The only objection to the word is that rheumatism is derived from the same root; but the fact that the new word has "neuro" prefixed, and the old one has no prefix, but has "tism" affixed, will serve sufficiently to separate them, whilst the difference between the adjectives neurorheumal and rheumatic is very marked. This phraseology would have the great advantage of tending to scientific accuracy of thought, and would also serve to impress upon the mind that the flow along a nerve is nothing but one of the many various ways in which energy can be manifested. Beginners in medical studies often fail to grasp this elementary fact; but if they were told that that form of energy which was peculiar to, and could only be manifested in, nervous structures was called "neurorheuma" they would have a clear conception to begin with, and would appreciate the relation of neurorheuma to other forms of energy. We should then be able to speak of the manifestations of energy as light, heat, electricity, neurorheuma, sound, motion, and so forth. It would also serve to emphasise the doctrine of the conservation of energy, for, as just remarked, it is not sufficiently recognised that the transmission of nervous energy, or, as we should now express it, the passage of neurorheuma, along a nerve is only a form of manifestation of energy. In proof of this, I may mention that Draper, in his Text-book of Medical Physics, in an enumeration of all the forms of energy, leaves out "nervous." Let us hope that the next time an enumeration is made neurorheuma will be included.

Neurorheuma, as it flows along a nerve, is, of course, kinetic; but it may be potential. For example, light falling on the retina is kinetic energy; this becomes transformed at the retina into kinetic neurorheuma, which passes along the optic nerve to the brain, where it is stored up. Let me give a fuller example of the use of the new word. A man, wishing to reproduce exactly as a drawing at home what he sees when he is out, will gaze long at the scene, by which means a large amount of light from it will fall on his retina; this will become converted into a considerable amount of neurorheuma, which, passing along the optic nerve, will be stored up in the brain as potential neurorheuma. When he gets home this will become kinetic neurorheuma, and will flow along his motor nerves to his brain, where it is converted into mechanical motion, with the result that the picture is drawn. It is to be noted that no attempt is here made to give a new explanation of facts; all I wish to show is that the adoption of the new term "neurorheuma" will facilitate the discussion of these matters.

In many respects neurorheuma is a peculiar form of energy, chiefly because it is presumably only capable of being manifested in nervous structures. But this peculiarity is one of degree rather than of kind, for electricity is conducted much better in some materials than others, whilst, as far as we know, neurorheuma has but one good conductor—viz., nerve tissue. Then, owing to the fact that this one good conductor is a living tissue, our power of experimenting with neurorheuma is necessarily limited. We should know very little of electricity if it could only be stored up and conducted in living tissues.

Another point requiring mention is that frequently the result is the same whatever be the stimulus applied, even if the application be not always at the end organ; thus, whether light falls on the retina or the stimulus be a mechanical one applied to the optic nerve the impression upon the mind of the individual is that of light. The discussion of this question is beyond the scope of this note; it does not affect the desirability of the term "neurorheuma" being applied to that form of energy into which in the one case light and in the other motion has been converted. It may be that there are different forms of neurorheuma: such as an optic neurorheuma, capable of transmission only along the optic nerve; an auditory neurorheuma, capable of transmission only along the auditory nerve; olfactory and gustatory, sensory to pain, sensory to heat; motor tactile neurorheuma, capable of transmission only along their respective nerves; to which there ought perhaps to be added trophic, secretory, and calorific neurorheuma, capable of transmission only along trophic, secretory, and calorific nerves respectively. There is much to be said in favour of such a view; it will explain why nervous actions always keep to one path, and also why any stimulation to the optic nerve, for example, causes light. Against such a view there is the fact that the axis-cylinders of these nerves are for the most part insulated by the fatty white substance of Schwann around them, which would be unnecessary if, for instance, a tactile fibre could only convey to the brain tactile neurorheuma; for it would be impossible for the tactile neurorheuma to overflow into a fibre which could only convey painful neurorheuma. But then it may be that the fibres are insulated to prevent the tactile neurorheuma from one tactile nerve fibre overflowing into another tactile nerve fibre. Again, if there be a distinct form of neurorheuma for each nerve, why is there an end organ—as, for example, the retina? But the obvious answer is that the object of the retina is to convert light into neurorheuma; for although a mechanical stimulus applied to the trunk of the optic nerve will cause a sensation of light, no amount of light concentrated on the cut central end of the optic nerve will cause this sensation. Still, although it is at present impossible to decide whether there be one form of neurorheuma which is differentiated by the cerebrum according to its source or destination, or whether there be all the various forms previously enumerated, the latter theory is a very tempting one to adopt, as it would explain many of our difficulties. There cannot be any doubt that the tissue of the brain is undergoing slow but continual change, for arterial blood having a certain chemical composition is being continually conveyed to it, whilst venous blood with an altered chemical composition comes

away from it; and it is no doubt difficult to understand how, if some molecules are constantly being carried away from the brain and others added to it, the neurorheuma stored up should remain. But may not the process be something of this fashion: as fast as a destructive chemical change goes on in any molecules in which neurorheuma is stored up, it is set free, but is immediately taken up again by the molecules resulting from the constructive chemical change that is continually going on. Possibly the exactitude with which this process takes place determines whether or not memory shall be good, for it undoubtedly might determine whether or not the neurorheuma should remain; so that, in pathological language, we should say that a person with a bad memory was one in whom the neurorheuma was not accurately transferred from the old molecules which were broken down to the new ones which were built up, whilst a person with a good memory was one in whom they were accurately transferred. Broadly speaking, it may be said, that a nerve is alive so long as it is capable of transmitting neurorheuma, and dead when it cannot do so; and probably we should be as near as possible to a correct definition of the distinction between life and death if we said that in the former the cardiac and respiratory nervous systems were capable of transmitting neurorheuma, and in the latter they were not.

My object has not been, however, to discuss these abstruse problems, but merely to suggest that the term "neurorheuma" is an advantageous one, as I hope I have shown by the use of it, and also to throw out the hypothesis that there may be not one but many neurorheumas.

St. Thomas's-street, S.E.

PERORATION TO MY REMINISCENCES OF FIFTY YEARS' STRUGGLE, IN THE FOOTSTEPS OF WILLIAM HARVEY, TO SEARCH OUT CRUCIAL FACTS IN PHYSIOLOGY.

BY T. WHARTON JONES, F.R.C.S., F.R.S.

A NOT uncommon incident in the history of institutions, how good and just soever their object may be, has been the formation of cliques who, having for the time got power into their hands, look to the serving of their own purposes rather than the honest fulfilment of the avowed object of the institutions themselves. John Wicliffe denounced the Church Courts of his time as dens of thieves and larders of hell, and their officers as subtle in malice and covetousness. In Ireland, where the ecclesiastical jurisdiction in Roman Catholic times had been even more corrupt and oppressive than in England or elsewhere, Bishop Bedell, of Kilmore, found, to his sorrow, the Ecclesiastical Courts still unreformed under the Protestant *régime*. Consecrated in September, 1629, he had not long entered on his sacred functions before complaints reached him of oppression and extortion suffered by the poor people in the Ecclesiastical Courts. This was the more grievous, seeing that the cause of complaint was given by the Bishop's own officers, and the wrongs committed in his own name.

In a letter to Archbishop Laud, at the time Bishop of London, Bishop Bedell complains of this oppression exercised by the Court Ecclesiastical, which, said he, "in very truth, my lord, I cannot excuse, and do seek to reform." His attempts at reform, however, stirred up against him the most virulent rage and malice on the part of the officers of Church Courts throughout the country, as well as of the chancellor of his own dioceses of Kilmore and Ardagh in particular. His right reverend brethren, the bishops, whose cause it was equally with his own, though they at first applied to him by way of compliment the saying of the Emperor Theodosius in respect to Ambrose, Archbishop of Milan, "Solus Kilmorensis novit se gerere ut episcopum," gave him no further countenance. This much mortified Bishop Bedell, for had his brethren joined in supporting the cause which so nearly concerned themselves and the well-being of the Church in Ireland, some better result might have accrued. Even Archbishop Ussher, whose Court was reputed to be as corrupt as others, if not worse, though he himself was so good a man, yielding to the influence of his chancellor, stood aloof. Turning again, therefore, to Archbishop Laud, Bishop Bedell wrote, saying: "For my part, God is my witness that if I thought I could be excused in conscience for the misgovernment of the people whom God and his Majesty have committed unto me, I could easily submit to be superseded in the exercise of the jurisdiction, though there be left me nothing but the name of it; when, however, the blame also and the shame of religion lie upon it, I hope good men will not account me pragmatical if I be sensible, and desire to fulfil the profession made at my consecration, that *I would be gentle and merciful, for Christ's sake, to poor and needy people and such as be destitute of help.* These poor people do beseech your lordship, and, by you, his Majesty, to pity them. Religion entreats you to remove this scandal—the Church to reform this disorder. I have said and done what I can; I leave the success to God."

Laud's reply to this appeal was sufficiently frank, friendly, and well-considered; but he thought that not much could be done, seeing that all the practitioners of the civil law were combined to resist any reform, whilst the bishops themselves tamely succumbed to the tyranny of their own officers. Under such circumstances, therefore, the said officers, "sotil in malice and covetisse" as they were, prevailed against the generous purpose of the heroic bishop, who was, among the faithless, faithful only found.

Wicliffe knew by experience the persecution which a translator of the Holy Scriptures into the vernacular brought down upon himself, but he could never have believed that in a Reformed Church opposition would have been offered to the translation of the Old Testament into Irish such as that which Bishop Bedell encountered. Indeed, the singular character of the opposition by churchmen; the subsequent narrow escape of the MS. from the hands of the Irish Roman Catholic rebels by the intervention of the Rev. Denis Sheridan, a Protestant minister, head of the Sheridan clan, and ancestral kinsman of Richard Brinsley Sheridan; its preservation for forty or fifty years by Bishop Jones, of Meath, previously Dean of Kilmore; its revision, as a labour of love, by an Irish convert to Protestantism, who had been a Jesuit professor in Spain, and Superior of the Jesuit Mission in Ireland; the eventual publication of the work under the auspices of the Hon. Robert Boyle; and its use, not only in Ireland, but also among the Gaelic-speaking people of the Scottish Highlands for nearly the whole of the eighteenth century,—form a curious history.

Bishop Bedell employed as chief translator a Mr. Murtagh King, who had been recommended to him as an able Irish scholar, and from whom he had himself taken lessons in the language while Provost of Trinity College. The bishop, thus satisfied of the competency of Mr. King to preach the Gospel to an Irish-speaking parish, admitted him to holy orders and collated him to a benefice. The poor man, however, was not only slandered, but positively robbed of his benefice on false pretences, and persecuted, notwithstanding all the protection the bishop could afford him. In a letter to Lord Deputy Wentworth, afterwards Earl of Strafford, urging a restitution to Mr. King of the benefice of which he had been so unjustly deprived, Bishop Bedell thus expressed himself: "The Bishops of Rome themselves, after most formal proceedings, do grant 'restitutionem in integrum,' and acknowledge that 'sententia Romæ sedis potest in melius commutari'"; adding: "My lord, if I understand what is right, divine or human, these be wrongs upon wrongs, which, if they reached only to Mr. King's person were of less consideration; but when through his side that great work, the translation of God's Book, so necessary for both his Majesty's kingdoms, is mortally wounded, pardon me, I beseech your lordship, if I be sensible of it."

In 1640 Bishop Adair of Kilala was, at the instance of the Earl of Strafford, brought before the High Commission Court on the frivolous charge of having spoken apologetically of his countrymen, the Scottish Covenanters, and sentenced to deprivation. At the trial, Bishop Bedell of Kilmore, as a member of the Court, in delivering his judgment, stood out for the most favourable construction of Bishop Adair's conduct, arguing that it involved no spiritual offence nor any error in life or doctrine such as may make a bishop deserving of censure. All the other members of the Court, however, gave their verdict against the Bishop of Kilala. According to what was alleged to have been the secret history of this transaction, the deprivation of Bishop Adair was a thing determined on for the purpose of creating a vacancy in the Irish episcopate for a Scottish bishop who had come to Ireland, a refugee from the anti-prelatic wrath of the Covenanters of Scotland.

In bravely standing up by himself in defence of a man unjustly prosecuted, Bishop Bedell was checked and chidden for his pains by the higher powers at the time, as a wilful and singular person to differ from the unanimous decision of *so honourable a Court!* Nevertheless, restitution by annulment of the sentence of deprivation passed against Bishop Adair and his appointment to another bishopric was subsequently made by command of King Charles I., when, after the death of Strafford, his Majesty came to be informed of the circumstances of the case.

Whether any reparation was ever made to Mr. Murtagh King does not appear, though it is most likely that he "dropped into the grave unpitied and unknown." A "memorial" of him, however, and that not a "frail" one, still exists in the Irish translation of the Old Testament. The man who was active in despoiling Mr. King of his benefice with the assistance of the corrupt Ecclesiastical Court, in order to get it for himself, was a refugee Scottish episcopalian minister, as was also the accuser of Bishop Adair of Kilala. The fate of these two worthies, however, was different—the former, notwithstanding the incredible injustice of his proceedings, being eventually made a bishop, whereas the latter was beaten to death by a band of Irish rebels.

The instances now related, as well as many others which could be quoted, exemplify how my ancestral cousin, Bishop Bedell of Kilmore, was opposed by falsehood, slander, fraud, forgery, and theft in his endeavours to fulfil the duties of his sacred office. The instances narrated in preceding numbers of THE LANCET, from among my reminiscences of a fifty years' struggle to follow in the footsteps of William Harvey in promoting physiological knowledge in its relations to medical science, may be compared, in a small way, *mutatis mutandis*, to the experiences of Bishop Bedell. The said instances also, I venture to think, warrant me in addressing, as I now do, the General Medical Council, Universities, Colleges of Physicians, Colleges of Surgeons, and all other authorities—whether individuals or bodies corporate—whom it may concern, to protest against the incongruous teachings by which the minds of students of medicine are distracted, and to urge a plea for their better instruction in a knowledge of fundamental facts—such, for example, as the observable mechanism and action of the vessels in the extreme circulation of the blood, regarding which their professors, under the auspices of the authorities I am addressing, seem to be ignorant either from incapacity or wilfulness.

To conclude, let those who think they know, without ever having looked to see, review their supposed knowledge and cast their thoughts over again; and if, in the particulars, they find they have mistaken words and fancies for realities, and accepted the dicta of pretenders instead of the evidence of observed facts, let them correct the record and acknowledge the truth as it is in nature. Moreover, let them remember that he who propagates a delusion, and he who connives at one when already existing, both alike tamper with the truth, and that we must neither lead nor leave men to mistake falsehood for truth. Not to undeceive is to deceive.

Ventnor, Isle of Wight.

ON THE TREATMENT OF ORCHITIS AND EPIDIDYMITIS.

BY FREDERICK W. LOWNDES, M.R.C.S.,
SURGEON TO THE LIVERPOOL LOCK HOSPITAL.

THERE is a sufficient diversity of opinion as to the best treatment of orchitis and epididymitis, the result of acute gonorrhœa, to induce me to give our experiences at the Liverpool Lock Hospital. When I first became surgeon, eleven years ago, I found that the practice adopted in all these cases was that which had been suggested by Mr. Furneaux Jordan in 1869—viz., by painting the affected testicle with a strong solution of nitrate of silver (two drachms to one ounce), at the same time enforcing strict rest in bed and supporting the inflamed organ upon a small pillow, so as to prevent it from hanging down. It had been adopted for some years previously by Messrs. Worthington and McCheane, who were the surgeons to the hospital at the time when Mr. Jordan suggested this mode of treatment; and also by Mr. Chauncy Puzey, who succeeded Mr. Worthington, during the two years of his surgeoncy. I have invariably pursued the same treatment now for eleven years, and so has my colleague, Dr. Armand Bernard, who succeeded Mr. McCheane in 1882, and has thus had four years' experience of the treatment.

At my request the resident superintendent of the hospital, Mr. Serjeant, has given me the following statistics of all the cases of orchitis and epididymitis combined from June 1st, 1875, to June 1st, 1886, an interval of eleven years. The numbers are as follows:—

Years.	Number.
1875 to 1876	32
1876 to 1877	15
1877 to 1878	22
1878 to 1879	28
1879 to 1880	30
1880 to 1881	16
1881 to 1882	31
1882 to 1883	28
1883 to 1884	24
1884 to 1885	18
1885 to 1886	25
Total	269

All these were patients admitted into the hospital; we have no out-patients.

I have always found the treatment I have mentioned most successful. The acute pain, often amounting to agony, is soon subdued, and in the majority of cases the testicle returns to its normal size in the course of a few days. Sometimes a second painting is necessary, but this suffices. In private practice I have always used the same application. When patients can be induced to take absolute rest in bed, the result is equally successful as in the hospital. When, however, patients are compelled to follow their usual occupations, the recovery must obviously be slower, as it is impossible by any suspensory bandages or by handkerchiefs, however skilfully applied, to ensure such perfect rest for the testicle as when the patient is lying in bed. I have heard it argued that rest in bed is sufficient of itself to effect a cure, but a very few cases so treated with spirit lotion as an application has convinced me that it is not so. The immediate effects of the nitrate in allaying the pain are most marked, though for obvious reasons the nitrate must act more powerfully upon the testicle while in a state of quiescence than when constantly moved, however slightly.

Mr. Jordan has informed me that he still pursues the same treatment, having every reason to be satisfied with it. It seems to me to be only just to him to give this very satisfactory proof of the value of the treatment which he originally suggested.

Liverpool.

CASES OF ORBITAL NÆVI TREATED BY ELECTROLYSIS.[1]

BY SIMEON SNELL, L.R.C.P. LOND., M.R.C.S.,
OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY AND TO THE INSTITUTION FOR THE BLIND.

THE following instances are good examples of the value of electrolysis in the treatment of nævus. One of them was more confined to the eyelid, but the others extended deeply into the orbit. It would not, I believe, have been easy to treat them with a ligature; and without discussing different methods of treatment, it may be doubted whether any other plan would have resulted in such an absence from deformity as was the case in these instances. A drawback, of course, to the use of electrolysis is that it may be necessary to repeat it several times. A feature in these cases is the similar situation in each.

CASE 1.—Rosina B——, aged three months, came first under my notice at the Sheffield General Infirmary in November, 1881. A nævus, apparently cutaneous, was situated in the upper eyelid, towards the inner angle, at its upper part. This was cauterised with the actual cautery, and the child disappeared. In June, 1882, she again came to me. The nævus had greatly increased in size; it was nearly as large

[1] Read before the Sheffield Medico-Chirurgical Society.

as a small walnut, and was plainly discernible as a swelling at the upper and inner angle of the orbit, pressing down the lid over the eye, and causing a good deal of deformity; it extended some distance into the orbit. It was determined to treat the case by electrolysis. Treatment was accordingly commenced on May 12th, when the needle was inserted three times; on the 26th and on July 3rd the process was repeated, the number of punctures being the same. At this latter date it was noted that the tumour was less than half its original size. After this it gradually dwindled, but the child, from ill-health, I believe, was only brought occasionally, and then not for active treatment. In 1883, the nævus was greatly reduced in size, and was hardened. On Jan. 22nd and Feb. 5th electrolysis was again resorted to, with the effect of dispersing the swelling. Later the mother came to inform me of the child's death from croup, and asserted that the tumour had quite disappeared.

CASE 2.—Beatrice H——, aged nine months, was first seen in November, 1884. The mother had perceived, in the previous April, a little dark patch at the inner side of the right upper eyelid. At the time of the baby being brought to the infirmary, at the upper and inner angle of the orbit was a purplish swelling about the size of a bean; it only showed itself on the surface, but extended more deeply. The mother thought it had not increased much in size since it was first noticed. On Dec. 1st treatment with electrolysis was commenced, three punctures being made with five cells; on the 8th and 15th, and also on Feb. 3rd, it was repeated. Soon after this last date it had disappeared.

CASE 3.—Jane L. E——, aged about three months, was brought to the infirmary in February, 1885. The nævus in this instance was larger than that in the last, but smaller than in the first-mentioned case. It was situated at the upper end and inner angle of the orbit, and extended deeply. The surface on the eyelid was purplish. The swelling became distended, as the others had done, on the child crying, and refilled after having been dispersed by pressure. It produced a good deal of deformity, and pressed the eyelid down over the eyeball at the inner side. The mother had noticed it only about a month before, and thought it had quickly increased in size. Exterior to it, at a little distance on the upper eyelid, was a small red-coloured cutaneous nævus. Treatment by electrolysis was commenced on Feb. 9th. Eight cells were employed and three punctures made; the superficial nævus was destroyed by the actual cautery. On the 23rd three punctures were made (ten cells); on April 20th, four punctures (twelve cells); on May 11th, four punctures (fifteen cells); and on June 1st, one puncture (fifteen cells), and three punctures (nine cells). The result was excellent.

CASES 4 & 5.—Since writing the above two other cases have been under treatment. Both occurred in young babies. One nævus, the size of an almond, was situated at the inner angle of the orbit, more on the nose than the eyelid. Electrolysis was repeated four times, and it disappeared. The other was as large as a half-crown, and occupied the left lower eyelid at the outer part and the cheek over the malar region. It is disappearing under electrolysis.

From six to ten cells of the battery will generally suffice; in Case 3 more were employed because the power of the instrument was deteriorating. A sufficient strength should be employed that will decompose water readily, and if this be tested before proceeding with the operation, it affords a simple plan of determining which needle to remove and which to keep stationary—the one from which the bubbles freely escape will be the one to use in the first manner.

CAMBRIDGE MEDICAL GRADUATES' CLUB. — The annual meeting and dinner of this Club was held at Caius College, Cambridge, on Saturday last, the 17th inst., Sir George Paget, K.C.B., a Vice-President of the Club, in the chair. Among the guests present at the dinner were the several professors of those collateral branches of science most closely connected with the study of medicine—viz., Prof. Newton (Comparative Anatomy), Prof. MacAlister (Human Anatomy), Prof. Dewar (Natural Experimental Philosophy), and Prof. Roy (Pathology). The Fellows of Cauis College then in residence were also present as guests of the Club, together with Mr. T. Pridgin Teale of Leeds. The principal speakers were the Chairman, Prof. Humphry, Mr. Timothy Holmes, and Mr. Teale. It was announced during the evening that the Club was in a most prosperous condition, having now close upon two hundred members.

THE INSUFFLATION OF IODOFORM INTO THE TRACHEA AFTER TRACHEOTOMY FOR DIPHTHERIA.

By GEORGE SHIRRES, M.B., C.M.,
LATE RESIDENT ASSISTANT SURGEON, ROYAL INFIRMARY, ABERDEEN.

WERE it not for the fact that after tracheotomy for diphtheria in children death is extremely common from the spread of the membrane down the trachea, the operation would be much more popular than it is at present. It is usually simple and successful enough as an operation, but the continuation of the disease in the trachea renders the final results far from satisfactory. After losing several cases from the above cause, it occurred to me that the insufflation of iodoform into the trachea after the opening of the windpipe might do something towards preventing the appearance of membrane there, and might thereby lessen the probability of death. The experiment proved eminently successful in the following two cases.

CASE 1.—I was called to see a boy aged four years and a half on the night of Nov. 2nd, 1885. I found the case to be typical of the so-called diphtheritic croup. The face was flushed, the glands beneath the angle of the jaw were enlarged, and his breathing was stridulous and performed with great effort. I advised instant tracheotomy, which the parents refused. I prescribed aconite, the use of the steam-kettle, &c., and left him for the night, very doubtful of his chance of life. When I saw him next morning the symptoms were intensified. The face was livid, the eyes staring, and the expression one of extreme anxiety. The sternum and anterior parts of the chest wall were retracted during inspiration. I insisted upon tracheotomy being performed, to which the parents consented, but with reluctance. I left for instruments and assistance, and on my return found the child in the same condition. I placed the patient under chloroform and opened the trachea. A large quantity of blood and membrane were at once expectorated through the wound, and the tube was without much trouble placed in the trachea. After this artificial respiration had to be resorted to, and was continued by my colleague, Dr. Bridger, for fully twenty minutes before respiration was properly established. Two hours after the operation I removed the inner tube, passed a thin insufflator down the outer one, and blew about ten grains of iodoform down the trachea. The child had a slight paroxysm of coughing, and, to judge from the expression of his face, seemed to experience a rather unpleasant sensation, but there was no worse result. The insufflation was repeated every four hours. Next morning I found the tube comparatively clear, but the temperature was 102·5°. Being rather afraid of iodoform poisoning I stopped the insufflation. During the day the tube got frequently clogged with membrane, and had to be removed and cleaned every two or three hours. At night I resumed the insufflation and repeated it every three hours, with excellent effect. At 3 o'clock next morning I was called by the patient's father, who, in attempting to remove the inner tube, had pulled the outer one with it. I found the patient in great distress, breathing through the wound with considerable effort. After some difficulty I reinserted the tube. From that time the patient rapidly recovered, and on the fifth day I removed the tube. The patient is now alive and quite well, with a slight cicatrix over the site of the wound.

CASE 2.—This was a somewhat similar case to the foregoing, although the symptoms were not so well marked. The patient was a little girl three years of age, whom I was called to see on the night of Dec. 10th, 1885. I found the patient suffering from symptoms of suffocation. The breathing was stridulous, the voice scarcely audible, the glands beneath the angle of the jaw enlarged, and the face much flushed. I recommended tracheotomy, and performed the operation that night. After the tube was inserted, I insufflated about fifteen grains of iodoform into the trachea, and repeated this procedure every four hours. The child made an uninterrupted recovery. On the third day I stopped the iodoform, and on the fourth removed the tube. There was no trouble with the wound, and recovery was perfect.

When iodoform is insufflated into the trachea, the cilia of the epithelium on the mucous membrane carry the

particles of iodoform upwards as far as the larynx, when they are expectorated with the mucus through the tracheotomy tube. I found that the best time to insufflate was just after the act of expiration.

LONDON HOSPITAL.

TWO CASES OF FOREIGN BODY REMOVED FROM THE FEMALE BLADDER; OVARIOTOMY FOR THE SECOND TIME; RECOVERY.

(Under the care of Mr. RIVINGTON.)

THE variety of foreign bodies introduced into the female bladder is large—in fact, the majority of calculi in the adult female are formed round some substance which has been introduced into the bladder by the patient. As a rule it is easy to detect and remove them through the urethra, with or without crushing, but occasionally, from the shape of the substance, it is necessary to remove them by vaginal or supra-pubic operation. In the first case it was necessary to perform the former operation, for the hair-pin had transfixed the bladder, and was immovable from the urethra. The third case, that of successful ovariotomy for a second time, is interesting from the fact that such operations are uncommon, it being a rare occurrence for the ovary left in a healthy condition at the first operation to become diseased.

CASE 1. *Calculus in the Bladder of a Female formed round a Hair-pin; Vaginal Lithotomy; Cure.*—Lavinia C——, aged twenty-two, single, was admitted on Nov. 27th, 1885. She complained of incontinence of urine, which had lasted for seven months. On examination, one end of an ordinary but rusted hair-pin was found protruding through the anterior wall of the vagina nearly in the middle line, whilst the other was found protruding rather higher up and to the right. Examination of the bladder with the sound showed that the pin was covered with a considerable incrustation of phosphates. The patient would not admit that she had introduced the hair-pin herself, but stated that eight months previously she had been out with a young man, and that afterwards incontinence came on, and she felt something pricking her. Under an anæsthetic an incision was made through the lower and central aperture caused by the protrusion of the hair-pin through the anterior vaginal wall, and the other limb of the hair-pin was pushed back into the bladder. The two limbs were then pressed together, and the whole mass was withdrawn through the vaginal wound. The opening was sewn up, and a catheter was not retained. The stitches were removed on Dec. 22nd, when it was found that the wound had closed, a small opening, representing the ulcerated aperture caused by the hair-pin, alone remaining. This was refreshed with the nitrate-of-silver stick and closed in a few weeks.

CASE 2. *Pen-holder in Female Bladder; Removal per Urethram; Cure.*—A. H——, aged eighteen, tie-maker, was admitted on Feb. 12th, 1886, suffering from pain and incontinence. It was stated that a pen-holder had accidentally entered the bladder whilst the patient was sitting down on a chair. On Feb. 16th the patient was anæsthetised and placed in the lithotomy position. The sound detected a hard body. The urethra was dilated with the index finger, which encountered the body lying across the bladder transversely to the urethral axis and firmly fixed. Six ounces of warm water having been injected, the pen-holder was shifted from its transverse position by means of the sound and was then seized with forceps and brought into the urethra. Here the nib of the pen caught in a fold of mucous membrane, which had to be nipped across before the pen-holder could be extracted. The instrument was found to be 3¼ in. long and was made up of a bone-handled stiletto used in ladies' fancy work, over which a barrel pen nib had been placed. It was partly encrusted with earthy phosphates. After the operation, the urine, which had been thick with pus and mucus, and was alkaline, gradually cleared and became normal, the incontinence ceased, and the patient was discharged on Feb. 25th.

CASE 3. *Ovariotomy for a second time; Recovery.*—S. B——, aged forty-three, married, was admitted under Dr. Down on Nov. 11th, 1885. Three years before she had had an ovarian tumour removed by Mr. James E. Adams, and had made a good recovery. Her abdomen was distended with ascitic fluid, and she suffered severe pain in her chest, abdomen, sides, and back; she hardly ever slept on account of the pain. Tongue furred and moist; no appetite; bowels regular; temperature normal; pulse 100; respiration 40; dyspnœa; circumference at umbilicus 36 in.; urine acid and free from albumen and sugar.

Nov. 14th.—Tapped; 340 ounces of fluid removed, with much relief.

18th.—Great pain in left leg and thigh; œdematous; superficial veins congested; phlebitis of femoral and saphenous veins.

Dec. 4th.—Tapped to 340 ounces. A firm lobulated tumour could then be felt in the right iliac and lumbar regions.

18th.—Ascites increased. Tapped to 335 ounces. Tumour distinct.

Jan. 7th.—Patient in a very critical state, with vomiting and retching. Pulse feeble; expression anxious. Tapped to 25 ounces, with relief.

8th.—Transferred to surgical side for immediate operation, which was performed under the spray. An incision three inches in length proved sufficient for the removal of the tumour after the evacuation of a large quantity of blood-stained ascitic fluid. The tumour itself was as large as a good-sized cocoa-nut, multilocular, and containing one large and three small cysts, of which one was bilocular. The large cyst was smooth outside, but inside was nearly filled up with a nodular papillomatous growth springing from the whole of the inner surface. The small cysts contained similar growths, and in one the growth had burst through the cyst wall and was fungating without any covering. The fungating mass was extremely vascular, and bled on the slightest touch. The growth was contained in the right broad ligament, and the ovary was not distinguishable. The stump of the former pedicle on the left side was examined, and found to be free from disease. The abdominal wall was extremely thin and the patient much reduced at the time of the operation. She recovered without a bad symptom. The temperature did not rise above normal. The wound was dressed for the first time at the end of a week, and was then nearly closed. The patient was discharged well on Feb. 25th.

EDINBURGH ROYAL INFIRMARY.

A CASE OF REMOVAL OF THE ENTIRE LOWER JAW BY THE MOUTH FOR ACUTE NECROSIS; REMARKS.

(Under the care of Prof. ANNANDALE.)

WE are indebted to Mr. Reginald E. Horsley, M.B., C.M., house-surgeon, for the following notes (by permission of Professor Annandale).

H. H——, aged seven, was admitted on Nov. 16th, 1885, suffering from great swelling of the face, and suppuration in connexion with the lower jaw. With the exception of an attack of croup and measles, the latter two years ago, the patient had enjoyed excellent health up to the date of the present attack, which began about ten days previous to admission, the child being at the time apparently in the soundest health. The family history is in every sense good, nor is there any record on either side of scrofula or syphilis. The present attack commenced with acute pain in the region of the last molar tooth on the right side of the lower jaw—i.e., the second molar of the first dentition, which, in common with its fellow of the opposite side, was carious. On Saturday, Nov. 7th, swelling in the region of the tooth mentioned was observed by the father, and two days later the patient, being seized with a rigor and suffering intense pain, became so feverish that he was obliged to remain in bed. On this day the swelling in the gum was noticed to have increased, and three days later burst into the mouth, discharging much pus. Next day, the patient's condition becoming more and more serious, a medical man was called

in for the first time. The tissues of the gum were now freely incised, and more pus escaped. On the following day, Nov. 14th, one week from the (observed) commencement of the attack, the father noticed a large portion of the lower jaw exposed, and the doctor extracted the two carious molars. Two days later, the lower incisors, being loose, were also extracted, while several other teeth dropped out. The child was then brought to the infirmary.

State on admission.—The lower part of the patient's face was much swollen, the soft parts over the lower jaw being red and glazed in appearance, and extremely tender to the touch. A most offensive discharge of fetid pus and blood oozed continuously from the corners of the mouth. Thorough examination of the jaw was difficult, owing to the swelling and tenderness, and to the fact that the mouth could not be fully opened. The temperature was 100·6°. The same evening the patient was very restless and complained of great pain.

Nov. 17th.—Temperature in the morning 101·6°; rose in the evening to 104·6°. There was much drowsiness; the offensive discharge continued to ooze from the mouth. The treatment consisted of warm fomentations externally, and frequent syringing and washing of the mouth with dilute Condy's fluid.

18th.—Morning temperature 103·2°; evening, 103·4°.

19th.—Morning temperature 105°. The patient being under the influence of chloroform, Professor Annandale made a thorough examination of the inside of the mouth, with the result that the entire lower jaw was found to be necrosed, its whole periosteum separated, and its connexion with the surrounding parts only maintained by some portions of the ligaments at the articulations. These ligamentous attachments being easily separated with the finger, the entire lower jaw, in one complete piece, was drawn out at the mouth, without any cutting or further procedure. Some slight oozing followed the removal of the bone, but this was soon stopped. In the evening the temperature had fallen to 100°, and the patient was comparatively easy.

20th.—Patient decidedly better. Morning temperature 99·4°; evening, 102°.

21st.—Morning temperature 102·4°; evening, 101·6°. Patient complained much of pain in the region of the right ear, from the external meatus of which fetid pus was seen to ooze. Slight diarrhœa.

22nd.—Morning temperature 102·2°; evening, 102°. Patient very restless, and much weaker. The discharge from the ear and the diarrhœa continued and increased.

23rd.—Patient much worse. Hæmorrhage from the mouth controlled by a styptic. In the evening he became delirious, with all the symptoms of meningitis.

24th.—The patient died, his symptoms having become gradually worse.

Post-mortem appearances.—No necropsy was authorised, but examination of the mouth after death revealed an intense and well-nigh complete disorganisation of the gums and soft textures on the floor of the mouth in immediate proximity to the position of the jaw. The periosteum was swollen and puffy, and in no part that could be felt was there any sign of an attempt to regenerate bone. The contour of the face was preserved. Examination of the jaw itself showed it entirely necrosed throughout its whole thickness. None of the teeth were present, all having dropped out or been extracted. On the left side the germ of the permanent molar was seen.

Remarks.—The interesting features of the case are—(1) the rapid and complete necrosis of the entire lower jaw without any apparent cause; and (2) the removal of the jaw, whole and unbroken, through the mouth. With respect to the latter point, the case is probably unique, no instance having been yet recorded of removal of the entire jaw through the mouth without incision or division of the jaw. There are certainly a few instances on record in which, after division of the symphysis, the jaw has been removed in halves, and other cases have been published in which considerable portions of the entire thickness of the jaw have been drawn through the mouth. Here, however, though the patient's mouth was by no means large, the jaw being carefully separated from its ligamentous attachments, was gently rotated, so as to permit the articular ends to be drawn alternately through the mouth. As regards the first point, it may be remarked that, while necrosis of the lower jaw, as the result of phosphorus-poisoning or some inflammation of a semi- or entirely chronic nature, is not without a place in the history of affections of this bone, total destruction of the entire substance in so short a space of time as twelve days or less from the first noted commencement of the disease, is sufficiently rare to be worthy of note. Not the least interesting feature, too, in the case is the apparent absence of any cause, or at least of any of the more usually recognised causes of necrosis. The most careful questioning failed to elicit any history of injury or cold, though, of course either may have acted in originating the disease, and escaped notice in the consideration of the disease itself. Erichsen (vol. ii., p. 577), while enumerating the ordinary causes of necrosis of the lower jaw—blows, salivation by mercury, syphilis, and phosphorus poisoning,—does at the same time admit that he has "seen the disease occur idiopathically in otherwise healthy subjects without any assignable cause." There is, it is true, a history of carious teeth, and the transition from caries of the teeth to alveolar periostitis and thence to necrosis of the jaw is a not infrequent one, but this state of things seems most usually to coexist with a strumous or scrofulous state of the constitution, and in the present case there is no record of such morbid state. Careful examination, however, yields two or three facts which are interesting, even though among them the real force which set the machinery of disease in motion be not discovered. Heath, in his work on Injuries and Diseases of the Jaws (chap. viii., p. 3), remarks, in speaking of necrosis, that "any ulcerative affection of the mouth may lead to necrosis of the jaw." Now the patient's father stated that the child had drunk from a wayside horse-trough in the village, and suggested blood-poisoning by means of a glandered horse. Glanders certainly affects the mouth in common with the rest of the respiratory tract, but there is no evidence to show that glanders and necrosis of the jaw can be regarded as cause and effect, putting aside the fact of the absence of other symptoms of this form of blood-poisoning. The question then arises: Could the disease have originated in some inflammatory action, leading to ulceration of the tissues of the cheek, and ultimately spreading to the alveolar periosteum? No evidence of any such condition exists. Indeed, the evidence is all in the opposite direction. The swelling of the face, which was certainly great, was subsequent to the severe pain (toothache) in the jaw; and the so-called gumboil, noticed by the father, was situated on the inner side of the gum, and not in apposition to the cheek. There remains yet to be considered the question of the cutting of a tooth of the second dentition; and here a ray of light, if a feeble one, seems to fall upon the case. It will be remembered that the germ of the permanent molar was seen in the jaw, and in connexion with this point the following remarks from Wedl may be quoted:—"Periosteal inflammations occurring during the period of dentition are of special importance, since, with children, inflammatory affections generally run a more rapid course than with older people, particularly in an organ in which development takes place within small limits with comparative rapidity. The more extensive the infiltration of the maxillary periosteum, the greater is the danger that a larger portion of the jaw will become necrosed. Children of a scrofulous or tuberculous habit are more liable to the occurrence of necrosis of the jaws, from the fact that in them the infiltration undergoes a speedy degeneration on account of the rapid proliferation of the elementary organs." Tomes also points out the occurrence of necrosis of the jaw during the period of dentition, particularly where a decayed tooth exists in the mouth and the child is of a scrofulous diathesis. Heath, too, remarks (*loc. cit.*) that "acute periostitis of the jaw may arise in young subjects from the cutting of the permanent teeth." Summing up, then, the facts presented, we have:—(*a*) Absence of usual causes; (*b*) absence of inherited scrofula; (*c*) presence of carious teeth; (*d*) appearance of first molar of second dentition. It is probable, then, that the cause of this interesting case may be found in the fact that the usual inflammation consequent on the cutting of a tooth passed to and affected the carious molar of the first dentition; that so alveolar periostitis was set up, leading to extensive necrosis of the lower jaw. But since most leading authorities lay stress upon the presence ordinarily of some constitutional taint, and since, as Erichsen (vol. i., p. 1061) points out, scrofula not necessarily inherited "most commonly declares itself about the period of the second dentition," it is equally possible to admit that a scrofulous taint, unsuspected and hitherto undeclared, lent itself to the

development of a disease which, notwithstanding the presence of carious teeth of the first and the conjoint cutting of a tooth of the second dentition, might otherwise never have ensued.

ST. VINCENT'S HOSPITAL, DUBLIN.

CASES OF ACUTE RHEUMATISM QUICKLY CURED BY SALICINE; REMARKS.

(Under the care of Dr. QUINLAN.)

THESE cases were reported by Mary Josephine Hannan, ward clerk.

CASE 1.—M. O'N——, wife of a warder in the Dundrum Lunatic Asylum, a strong, well-nourished young woman, aged twenty-six, was admitted on May 21st. She was in a high fever, the temperature being 101·2°, and the pulse 92. She was in great pain, and was sweating profusely. The right knee and right foot were swollen, red, and fluctuating; the left knee was also considerably swollen. She had been ill for three days, the symptoms gradually increasing in severity. She was ordered twenty grains of salicine suspended in milk every two hours, also at once a hypodermic injection of one-fourth of a grain of acetate of morphia.—6 P.M.: Pain somewhat relieved, but temperature had risen to 102·1°. The salicine to be increased to thirty grains every two hours. To repeat the hypodermic injection of morphia at 10 P.M.

May 22nd.—9 A.M.: A rather uneasy night. The left knee and both wrists are swollen, red, and painful. Temperature 103·2°; pulse 104. Considerable perspiration. Patient is unable to move hand or foot. The hypodermic injection of morphia to be repeated and the salicine continued.—6 P.M.: The patient is much relieved. Temperature 102·6°; pulse 96. Not able to move, but not in pain when motionless. To continue the thirty-grain doses of salicine every two hours.—10 P.M.: To take the following draught: twenty grains of chloral hydrate, thirty of bromide of potassium, an ounce and a half of cinnamon water, with a drachm of syrup of orange.

23rd.—9 A.M.: Passed a good night; free from pain, but unable to move. Temperature 102·8°; pulse 108. The salicine to be increased to thirty-five grains every two hours.—6 P.M.: Very much relieved; great fall in the temperature, which is now 101·4°; pulse 100. To repeat the chloral draught. The salicine to be taken during the night, as opportunity arises.

24th.—Passed a very good night; free from pain; temperature 101·6°, pulse 96.—6 P.M.: Going on satisfactorily. Temperature 100·9°; pulse 88. Reduce the salicine to twenty grains every two hours. Repeat the chloral draught.

25th.—Temperature risen to 101·6°; pulse 100. A good deal of pain. To resume the thirty-grain doses of salicine every two hours.—6 P.M.: Temperature 101·2°; pulse 90.

26th.—Greatly improved; quite free from pain. Temperature 99·4°; pulse 78.—6 P.M.: Temperature 99·6°; pulse 76. At 10 P.M., the patient being inclined to sleep, no draught was given.

27th.—Passed a very good night. Temperature normal; pulse 78. Totally free from pain. Twenty-five grains of salicine every three hours.—6 P.M.: Temperature 98·8°; pulse 84. Patient comfortable and free from pain.

28th.—Temperature normal; pulse 76. Able to move limbs slightly. Swelling of joints beginning to diminish. Thirty grains of salicine every four hours.

During the 29th, 30th, and 31st the pulse and temperature continued normal, and the articular swelling disappeared.

June 1st.—Patient able to sit up in bed. To continue the thirty-grain doses of salicine three times a day.

4th.—Patient convalescent and able to get up. To continue the salicine night and morning for a week.

CASE 2.—M. M——, aged thirteen, a schoolgirl, was admitted on June 10th, suffering from acute rheumatic symptoms. She was very feverish; temperature 101·1°; pulse 92. Right knee swollen, fluctuating, and painful, but not red. Could not move the right foot, which was somewhat swollen; sweating a good deal. Ordered ten grains of salicine every third hour.

June 11th.—Rather better. Right knee and foot in the same condition. Temperature 100°; pulse 88. Perspiration ceased. Had slept well. To continue salicine.

12th.—Greatly improved. Temperature 99·4°; pulse 84. Able to move the right knee and foot a little.

13th.—Had slept well. Temperature and pulse normal. Able to move the right leg freely. Ordered to sit up in bed, and to continue the salicine three times a day.

15th.—Convalescent. To get up. To continue the salicine night and morning for one week.

Remarks.—The first case was of a very acute type, and increased in severity after the patient's admission to hospital. The temperature, the pulse, and the symptoms generally were kept in complete control by the salicine, the administration of which was strictly regulated by the clinical thermometer. Under the old methods of treatment it would probably have run on to five or six weeks, and possibly might have been attended with cardiac complications. In the present instance complete relief was obtained in a week and convalescence in a fortnight. The heart was carefully examined with the stethoscope morning and evening with a view to the early detection of any heart lesion, but nothing of the kind was met with. From the fact of the patient lying perfectly quiet in the horizontal position, and being more or less under the influence of morphia (to gain time while the salicine was acting), cardiac mischief might advance to a considerable extent without the patient noticing any difficulty in this respect. To prevent relapse the salicine was continued for three weeks after convalescence; first, three times, then twice, and finally once a day. The second case was of a mild character, and presented no difficulties in treatment. There is no doubt, however, that its progress was considerably abridged by the salicine treatment, which appeared at once to control the rheumatic symptoms, which in the beginning were, as far as the right knee was concerned, rather severe.

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

Intra-uterine Polypus.—The Curette in the Diagnosis and Treatment of Intra-uterine Disease.—Labial Hæmatoma.

A MEETING of the Obstetrical Section was held on May 7th.

Dr. BYRNE exhibited a small intra-uterine polypus lately removed from a pluripara, aged thirty-seven, under his care in St. Vincent's Hospital. The dilatation of the cervical canal was commenced with sea-tangle tents and finished by Hegar's dilators, and the polypus removed by an écraseur.

In the adjourned discussion on Dr. W. J. Smyly's paper on the Curette in the Diagnosis and Treatment of Intra-uterine Disease, Dr. ATTHILL said that some years since he had been stoutly opposed to the use of the curette. Now, however, he had changed his opinion, as well as others which he formerly entertained. He now looked on the curette as a most useful instrument, and freely employed it in many cases. The principal question was, ought they to use the curette as a diagnostic means without previous dilatation of the uterus, or ought they to dilate the uterus first and use the curette afterwards? He believed, however, that the instrument was appropriate only to a certain proportion of cases. If the patient were a woman who had had several children, and who had a patulous cervix through which a finger could be thrust, and if she were suffering from a thickened and unhealthy mucous membrane, a small curette might be introduced without any anæsthetic, and the bleeding part removed. Generally, there should be dilatation first and then the use of the curette; but there were cases in which the curette, without previous dilatation, as a diagnostic process, was justifiable and advisable. In many cases it was impossible by any digital examination to ascertain what was the exact condition of the fundus. He believed that, for twenty years, in no case in which there was hæmorrhage, and in which he found no polypus, had he applied nitric acid without first using the curette. He agreed with Dr. Smyly that the curette *per se* was safer than dilatation. With a soft cervix dilatation was perfectly safe, provided antiseptic precautions were used. But there was danger in dilatation if attempted rapidly with a rigid cervix, neglecting antiseptic precautions. Most serious symptoms resulted from attempts to dilate the uterus where there was an exceedingly rigid cervix. He would

almost prefer to divide the cervix in such cases. Dr. Smyly objected to the use of powerful caustics, for three reasons—namely, that they necessitated previous dilatation, that their action was rendered uncertain by the discharges, and that they destroyed the tissues. But for many years he (Dr. Atthill) had used nitric acid very generally without dilatation; and whenever he used the curette his practice was to apply nitric acid or some other agent at the end of four or five days, and through a cannula. He now frequently used intra-uterine injections, usually iodised phenol or iodine, though in his earlier lectures he denounced the introduction of any fluid into the uterus.—The PRESIDENT said there appeared to be a general concensus of opinion in favour of using the curette in the manner recommended by Dr. Smyly. Nevertheless, he wished to say that he dissented from the views which Dr. Smyly had so temperately put forward. He was of opinion that the curette was a very dangerous instrument and liable to great abuse, and one from which no diagnostic information could possibly be derived. He could see no therapeutic or diagnostic advantage to be derived from scraping a mucous membrane with the curette. Was such a therapeutic agency recommended in the case of any other mucous membrane in an inflamed state by way of soothing or relieving the inflammation? If the mucous membrane of the bladder were in a state of inflammation, he could not conceive that it would be relieved by scraping. He thought that recovery in the cases in which the curette had been employed had taken place in spite of its use, and that the beneficial results were due to the additional treatment that had always been adopted.—Dr. NEVILLE said he concurred in Dr. Smyly's views as to the curette. There was considerable experience of the utility of scraping other mucous membranes besides that of the uterus. The scraping of granular eyelids was an old and very efficient practice. Such treatment was founded on rational grounds, and the amount of success which had attended it proved that it was good.—Dr. SMYLY, in reply, said the points he laid stress on were the use of the curette in diagnosis, and its use as compared with other methods of treatment. Dilatation was not necessary in every case before applying the curette, although it might be in cases where polypus existed. The great majority of cases of hæmorrhage were connected with disease of the mucous membrane, and diagnosis by the curette should be limited, as far as possible, to the mucous membrane. He believed the curette to be a more accurate instrument of diagnosis than the finger. In all the cases mentioned in his paper he meant to convey that he removed mucous membrane.

Dr. DILL read a communication on a case of Labial Hæmatoma. The patient was a primipara, aged twenty-one, and her labour had been completed without artificial aid. Shortly after delivery her medical attendant noticed a rapidly growing tumour in the right labium. This tumour, when seen by Dr. Dill an hour subsequently, had attained a size somewhat larger than that of a large fœtal head. On the internal surface of the tumour—i.e., within the vulva—the finger came upon a thin membranous covering which immediately ruptured, exposing a huge cavity filled with a quantity of clotted blood. After removal of the clots the cavity was filled with pledgets of lint soaked in carbolic solution, and the whole made as secure and comfortable as possible. No further hæmorrhage resulted, and the patient gradually rallied from the shock, which had been very severe. The ecchymosis resulting from this hæmatoma extended round the buttocks, and as far down the right thigh as the knee: it also spread over the abdomen on both sides as high as the level of the umbilicus, and on the right side almost into the axilla. Frequent changes of dressings were required at first, and much comfort was afforded by hot stupes and poultices. Hot antiseptic irrigations were employed twice daily, and the patient rapidly gained ground after the first fortnight, being finally completely restored to health. Dr. Dill had seen several cases of labial hæmatoma in his practice, but never one of the size recorded, nor one which had caused such severe symptoms in the way of pain and collapse.—Dr. Atthill said these cases were generally divisible according as the blood was entirely poured out into the labial tissues, or those in which the hæmatoma burst and profuse external hæmorrhage ensued. Dr. Dill's case, he thought, was one of the former class, in which the blood was poured into the soft parts and coagulated there. It was remarkable for the very unusual size attained by the resulting blood-tumour.

FORFARSHIRE MEDICAL ASSOCIATION.

THE twenty-ninth annual meeting of the members of this Association was held on the 8th inst. at Montrose Asylum, when office-bearers for the ensuing year were chosen as follows:—President: Dr. Lawrence (Brechin). Vice-Presidents: Dr. John Mackie, jun. (Brechin), and Dr. Greig (Dundee). Secretary: Dr. Stalker (Dundee). Treasurer: Dr. Reid (Dundee).

Dr. HOWDEN then read a paper on Hospital Sanitary Arrangements, which he illustrated by means of several excellent diagrams. The author, at the outset, remarked that he did not propose to discuss hospital sanitation generally, his object being to draw attention to defective sanitary arrangements which might exist in hospitals and asylums, and to point out how these might be remedied. He thought he might safely affirm that no hospital or asylum built twenty or more years ago would, in its original arrangements, be found to be altogether in accord with modern sanitary views. To illustrate the errors that were committed thirty years ago he need not go beyond the walls of that institution in which they were met, though he thought it not unlikely that errors of a similar nature might be found to exist in other institutions of a similar date. The introduction of water into a dwelling was not always an unmixed good, and had, indeed, owing to the ignorance of the architect or the carelessness of workmen, often been followed by serious evils to the health of the inmates. Even to this day architects were fain to conceal water-cisterns in dark and most inaccessible parts of the roof. Pipes of all kinds were hidden from sight, and too often sewer drains were brought under floors and joined with soil-pipes in situations where they could have no security that the connexions were properly closed. Situated as Montrose Asylum was, at a distance from any general system of town drainage, utilisation of the sewage by irrigation or precipitation was almost a necessity. Irrigation as carried on thirty years ago implied the collection of the sewage in a large cesspool, whence the more liquid part of it was pumped on the land. As was the practice, they made a large cesspool, into which the sewers were run directly without any attempt to trap or disconnect them from the house. Sewage, when conveyed directly to the land in well-ventilated drains, was almost odourless, because it had no time to undergo decomposition. A very different material, however, was sewage when allowed to become stagnant in a cesspool, where it undergoes changes involving the liberation of sewage gas, which, in their case, found its way into the house whenever there was a defective drain. In laying the original drains several mistakes were made. The pipes were much too large—12 inches in diameter,—so that they could never be properly flushed. The work was done carelessly by a contractor, who sometimes neglected to allow a proper fall for the pipes, and often left lumps of cement projecting from the inside of the facet, so as to obstruct the passage of solid matters. Connexions and disconnexions were often incomplete, joints were left open, and pieces of old drains now disused were not removed. Drains of all kinds passed from the back of the building to the front, intercepting in their course soil-pipes inside the building. The main soil-pipes, which were of lead, were closed in recessed flues in the wall, and, as was afterwards discovered, the slip joints were in some cases not even closed. Not unfrequently the branch pipes were not trapped, so that they formed efficient ventilators to the drains into the wards. Some of the w.c. traps were conducted into a horizontal lead soil-pipe, which was unventilated, and as a consequence the sewer gas perforated the upper portions of it; but as the whole arrangements were carefully boxed in, no one was the wiser save for the bad smells and the abundance of rats which swarmed in all directions. After detailing the improvements which of late years have been made in the drainage of the institution, Dr. Howden proceeded to review the interior arrangements, in the course of which he remarked that with regard to concealed pipes, it was well known that water-pipes were often cut by rats, and the plumbers' theory was that they gnawed the pipes, to get at the water. That he believed to be quite a fallacy. They did not require to leave their drain in search of their favourite beverage. They cut the water-pipe simply because it obstructed their passage, and so, in like manner, if it happened to be a gas-pipe which was in their way they would cut it, thereby causing unknown waste of gas, and

infinite risk from fire; for the gas, unlike the water, did not show itself, but found its way up the back of the plaster to the roof, or passed under floors and even into chimneys. In concluding, the author said he considered it of the utmost importance that the managers of every hospital and asylum should possess an accurate plan of the sewers, drains, and other sanitary arrangements of the institutions under their charge. Without that he knew from experience that alterations made to remedy evils often multiplied and aggravated them, and as one generation of officials passed away so did much valuable knowledge, unless it was carefully recorded on an accurate plan. Of late years public attention had been thoroughly aroused to the dangers of defective sanitary conditions in private houses. Sanitary inspectors had been appointed, sanitary associations formed, and sanitary institutions established; engineers and plumbers vied with each other in the contrivance of clever sanitary appliances; even architects were beginning to recognise the fact that their customers nowadays actually expect that a house shall be a healthy dwelling; and it was not too much to expect that the medical profession, which had always led the van in sanitary reform, should require that their patients, when congregated together in large numbers under one roof, should have the full advantage of those healthy surroundings which were considered so important in private dwellings.

The members of the Association were afterwards entertained to dinner by the directors of the asylum, when between fifty and sixty gentlemen sat down, Dr. Howden presiding.

Reviews and Notices of Books.

A Manual of Surgery. In Treatises by Various Authors. Edited by FREDERICK TREVES, F.R.C.S., Surgeon to, and Lecturer on Surgery at, the London Hospital. In Three Volumes. London: Cassell and Co. 1886.

THE three small, handy volumes of which this work consists are the result of the labours of no less than thirty-three writers, including the editor. All of them are surgeons more or less known to the profession as authorities on the subjects of which they treat, or whose names are guarantees of the excellence of the treatises written by them. The volumes contain about six hundred pages, and each is the size of the clinical manuals issued by the same firm of publishers. From the size of the volumes it has evidently been difficult for the writers to limit their treatises to the number of pages allotted to them; some of the treatises, in fact, appear to be abridged from works already written by the authors, which occupy the space of one of the volumes of the Manual. The title of the work is somewhat misleading until the preface has been read. There it is stated that "the three volumes of which it is composed are concerned mainly with the clinical, diagnostic, and therapeutic aspects of surgery. The general principles of operative surgery are dealt with, but the technical details of the various procedures are omitted, with the exception of such as concern what may be called special operations—namely, tracheotomy, gastrostomy, nephrectomy, ovariotomy, and the like. In similar manner, pathology is discussed only in so far as it affects the clinical phases and the intelligible treatment of surgical disease." As this is a Manual of Surgery intended for the use of the student and the practitioner, it would have been better to have included information regarding the operations ordinarily required sufficient to have enabled the former to pass his examinations and prepare himself for practice, and the latter to go for reference when in any doubt as to the special operative treatment of any particular case under his care. As it is, the use of this Manual must be supplemented by at least two others—one on pathology and the other on operative surgery. Looking at the work from the standpoint given in the preface, we acknowledge that the treatises are well, though unequally written, as might be expected. Indeed it would be almost impossible to find at present any work in which the subjects treated of are written more clearly or concisely.

The first volume contains treatises on the process of repair, general injuries and their results, wounds, contusions, abscesses, ulcers, gangrene, the general principles of operative surgery, anæsthesia, shock, tetanus, erysipelas, pyæmia and septicæmia, traumatic fever, hectic, gunshot wounds, the effects of heat, traumatic delirium, hysteria, scrofula and tuberculosis, rickets, hæmophilia, syphilis, gonorrhœa, tumours, injuries and diseases of bloodvessels, aneurysm, injuries and diseases of the lymphatics and nerves, surgical affections of the skin, scurvy, and animal poisons. The first paper is on the process of repair. It contains also a short account of the germ theory and the general principles of antiseptic treatment. It is clearly written, with the exception of the following paragraph, which requires alteration, as in its present form it hardly conveys the right impression:—"An injury is the result of the application of an irritant. The irritant may be applied directly to the part or indirectly. In the latter case it acts through the nervous system. For example, abscess of one of the cervical glands may result directly from a twist or strain of the neck, or *indirectly* from the irritation of a carious tooth, one of the commonest causes of abscess in that region. Or, again, a swollen testicle may result directly from a blow, or *indirectly* from a gonorrhœa." The italics are ours. Ten pages only are given to the general principles of operative surgery, which is treated of in a practical manner. We wish it had been a longer paper. Surely it is hardly necessary to devote nearly six pages in the third volume to the subject of extraction of teeth, when only ten are given to such a wide subject as operative surgery. The paper on anæsthesia is complete, and we agree in the main with the author, but advise the use of ether in routine practice for the adjustment of fractures. Those on syphilis, tumours, injuries and diseases of the bloodvessels, and aneurysm are good and practical, the one on the circulatory system being especially clear and well arranged. The absence of illustrations in the article on tumours detracts from the value of the paper, and contrasts with the article on animal poisons at the end of the volume, where there are several. The part which treats of injuries and diseases of the lymphatic and nervous systems will be read with pleasure. In the latter is a good account of Charcot's disease.

The second volume treats of fractures, but we note that fractures of the skull, spine, and ribs are dealt with in the injuries of the special regions to which they belong. The author dwells upon the treatment of fractures of the lower extremity by plaster-of-Paris splints; this is important, as they are coming into such general use. Diseases of the bones occupy about fifty pages; we dissent from the author, however, when he says that in the osseous lesions of congenital syphilis local treatment is uncalled for, the treatment by splints being so often necessary to give the part rest, and to prevent deformity. Injuries of joints, including dislocations, and diseases of the joints, take up space which is carefully and well utilised. In the description of the latter the author discusses some of those affections of the joints usually described as medical—e.g., gout and rheumatism,—which are apt to be forgotten by the practitioner when they affect one of the larger joints. Several of the illustrations in the work might with advantage be omitted in the next edition, and this remark applies especially to one which is found in the article on orthopædic surgery, "Talipes Calcaneus: the Foot before and after section of the Tendo Achillis." It is misleading and confuses the student, who would be apt to get the impression that that is the proper treatment of the deformity. Injuries and diseases of the head, spine, and neck are discussed, and the volume ends with papers on diseases of the nose, ear, and eye, which are tersely and well described. We notice that the author of the paper on

diseases of the neck arranges goitre into congestive and neoplastic, not following the usual classification.

In the third volume we find clearly written treatises on the surgery of the chest, affections of the mouth, palate, tongue, and tonsil (the latter opens with a clear description of the way in which malformations of the mouth and neck arise), diseases of the jaws, dental surgery (in which article we should like to have found more information regarding the temporary treatment of painful conditions so often met with in general practice), injuries and diseases of the œsophagus and abdomen, hernia, diseases of the rectum, breast, genito-urinary organs, and kidney. The treatise on hernia is thoroughly and clearly put together; that on the female generative organs, one of the articles written by the editor, is marked by characteristic excellence. The other articles, especially that on the kidney, contain in a condensed form the latest views on the subject, both from a clinical and an operative standpoint, and in that on the kidney the author is permitted to describe the operative treatment of the diseases on which he has already written.

At the end of each volume there is a short index, that at the end of the third including those of the first two volumes. The editor has had a difficult task to accomplish in the production of this work, and we congratulate him on the successful result.

OUR LIBRARY TABLE.

A Manual of Medical Jurisprudence. By ALFRED SWAINE TAYLOR, M.D., F.R.S. Eleventh Edition. Edited by THOMAS STEVENSON, M.D. Lond. Pp. 837. London: J. & A. Churchill. 1886.—That the above manual has reached the eleventh edition is in itself trustworthy evidence of its intrinsic merit and the favour in which it is held by the profession. The lamented death of its illustrious author has necessitated that the work of revision should fall into other hands, and, fortunately, the publishers have been able to secure the aid of Dr. Stevenson, whose practical acquaintance with the subject, especially in its toxicological aspect, is recognised and appreciated by practitioner and student alike. The style of the book remains unaltered, but many passages have been condensed, obsolete ones have been omitted, and "much additional matter has been introduced." We notice a succinct account of the Lamson case of poisoning by aconitine. Had the edition been delayed in its appearance for a short time, it would doubtless have contained a history of the trial (reported in this journal) which recently took place at the Old Bailey, where two persons were indicted for having compassed the death of a third by means of *liquid* chloroform. In the "List of Cases Cited," a ready aid to the reader, as it is separate from the general index, no mention is made of the "Euston-square Mystery." This is to be regretted, since the case, amongst other features of forensic interest, furnished valuable evidence on the question of personal identity. From a careful perusal, we can say without hesitation that we know of no similar work in our own or any other language in which the practical as distinguished from the theoretical aspect of the study of medical jurisprudence is handled with the same aim and attainment. The description of the methods of procedure to be followed for the collection and rendering of evidence is especially good.

What is Consumption? By G. W. HAMBLETON. London: J. and A. Churchill. 1886.—The answer supplied by the author of this *brochure* to the question stated in its title is a simple one. He rejects one after another all previously accepted theories upon the nature of phthisis, from the bacillus backwards, and arrives at the conclusion that the essential underlying cause is diminished pulmonary capacity induced by artificial modes of life, sedentary occupations, tight clothing, and the like. In his view, then, consumption is not only an acquired disease, but one which by due attention to the conditions favouring natural physical development might be eradicated. The very simplicity of the doctrine constitutes its chief attraction, and as the thesis is maintained with commendable brevity our readers might do worse than make themselves acquainted with it. The author himself is very strongly impressed with the truth of his doctrine.

An Account of a West Indian Sanatorium, and a Guide to Barbadoes. By the Rev. J. H. SUTTON MOXLY, Chaplain to the Forces. Pp. 209. London: Sampson Low and Co. 1886.—This volume was written in anticipation of the Indian and Colonial Exhibition, the author being desirous of bringing to notice "the great salubrity of the island, and the beneficial effects on invalids of a brief visit to the place." It appears to be a good guide-book to the various places worth visiting in the island, but we have failed to find in it any information which would justify the recommendation of Barbadoes as a sanatorium, beyond the statement of the author that he has convinced himself "of the wonderful salubrity of the island, and of its peculiar fitness, especially during the winter months and those of spring and early summer, as a place of resort for invalids suffering from pulmonary or throat affections, or from general debility." He also asserts that it is the healthiest station at which British troops are quartered, a statement which we believe to be quite incorrect. His own description of the sanitary condition of the island is by no means reassuring. "There is no system of drainage in Barbadoes outside the garrison. Bridgetown itself is undrained; old-fashioned cesspits serving, or being supposed to serve, to convey the sewage, by infiltration, to the sea." In the country districts matters are still worse, for the water-supply is derived from wells and from surface streams and ponds "whose condition is often loathsome." The author states, however, that active measures are now being taken to ensure an abundant supply of pure water being brought within reach of every household. The state of the profession in Barbadoes is eminently unsatisfactory. Speaking of the medical practitioners, our author says: "There are many mere charlatans; men who, having spent their youth behind the counter of a general store or in similar employment, have gone to America for a few months, and, returning with 'bogus' degrees, or, those of some unknown 'college,' set up as physicians and surgeons, and trade chiefly upon the simplicity of the lower classes and negroes." By an Act which was recently passed, a three years' course of medical study is required before anyone is allowed to practise, "but the terms of the Act are somewhat lax and indecisive as to what constitutes a course of study of medicine"; it is, however, a step in the right direction. We regret to observe that the author does not appear to have appreciated the value of an index to his work.

New South Wales and Victoria in 1885. By DOUGLAS M. GANE. Pp. 207. London: Sampson Low and Co. 1886.—We cannot say that this volume has added to our knowledge of the Australian colonies. A chapter on "Australia, and the Voyage thither, considered in regard to Consumption," appears to have been written under the impression that it is by no means unusual "carelessly" to advise invalids in an advanced stage of consumption to take a voyage to Australia in the hope of regaining health. If this impression were correct the somewhat sensational description of the risks and discomforts of the voyage under such circumstances might do good; but, as we believe it to be quite erroneous, we can only regret that the author did not take a little trouble to ascertain the truth before bringing a charge of ignorance and carelessness against the profession. The chapter on "Fortune-seekers and their Chances" may be read with advantage by any young men who think of emigrating to Australia with the notion that fortunes are made there

more easily than they are at home." The most interesting chapters in the book are the last two, which treat respectively of sport on the Blue Mountains of New South Wales and on the plains of the interior.

El Himen en México. Estudio hecho con unas Observaciones presentadas en la Cathedra de Medicina Legal en la Escuelade de Medicina el año de 1882. Por FRANCISCO A. FLORES. (The Hymen in Mexico. A Study with Observations made in the Chair of Forensic Medicine in 1882.)—Dr. Flores finds that the organ in question varies in form according to the age of the individual. Thus the labial form occurs in 35 per cent. under ten, and in 26 per cent. above that age; while the annular form occurs in 32 per cent. both of cases under and of those over ten years of age. The semilunar form is found in 16 per cent. under ten and 21 per cent. above ten; the fringed in 2 per cent. under ten and 5 per cent. above ten; the horse-shoe form in 2 per cent. under ten and 5 per cent. above ten; the various anomalous forms described by the writer as biperforate, imperforate, operculated horseshoe, trifoliate, multifoliate, and corolliform, were found in 10 per cent. under ten and in 4 per cent. above that age. His theory is that the membrane is originally formed from the two oviducts, and is always in the first instance entire, reabsorption subsequently taking place, usually commencing at the junction of the two primitive halves, and continuing to progress till puberty or even beyond it. The anomalous forms are, he thinks, due to a twisted condition of the primitive tubes, which causes the line of junction to be directed obliquely with reference to the middle line of the body. The work is written in a fairly scientific spirit; but some of the plates might surely have been made somewhat less realistic without detracting from their technical value for questions of a medico-legal nature.

A Manual of the Diseases of the Eye. By C. MACNAMARA. Translated into Bengali by LAL MADHUB MOOKERJEE, L.M.S., F.C.U., Teacher of Ophthalmic Medicine and Surgery in the Campbell Medical School. Calcutta, 1885. The appearance of this work must be regarded as a high compliment to Mr. Macnamara, and no doubt he will consider it to be so. It will at least serve to spread a knowledge of sound medicine and surgery as applied to the eye amongst the natives of India, and will enable them to judge of the advantages of European knowledge and skill over the rude methods we believe to be still in use in many of the more remote regions.

Handbook for Medical Officers of the Army. By J. BUCKLEY, Q.M., Medical Staff Corps. Pp. 47. Aldershot: J. May. 1886.—This is a small work compiled by the adjutant at the depôt of the Medical Staff Corps at Aldershot, which must be very useful as an *aide-mémoire* to the army medical officers. It gives in the smallest possible space the necessary instructions respecting squad, company, battalion, and stretcher-bearer drill; questions on military law, discipline, &c., and a summary of Section 3 of the medical regulations. It has been drawn up entirely from official sources, and contains a great amount of useful information in a very condensed form. It cannot fail to prove a useful departmental handbook.

The Journal of Physiology. Edited by MICHAEL FOSTER. Vol. VII., Part 3. Cambridge Scientific Instrument Company's Works, St. Tibb's-row, Cambridge—This part contains—(1) Bayliss and Bradford on the Electrical Phenomena accompanying Secretion in the Skin of the Frog; (2) J. W. Barrett on the Distribution of Bloodvessels in the Retinæ of Mammals; (3) C. A. MacMunn on the Presence of Hæmatoporphyrin in the Integument of Certain Invertebrates (with a plate); (4) M. Greenwood on the Digestive Process in some Rhizopods; (5) S. Politzer on Curara (with a plate), and also on the Physiological Action of Peptones and Albumoses.

Cookery for the Sick and Convalescent, with directions for the preparation of Poultices, Fomentations, &c. By BARBARA THOMSON. Pp. 76. Edinburgh: Blackwood. 1886.—This small book will, we believe, be found very useful, containing as it does a large number of receipts, with full and clear instructions for the preparation of appetising and nourishing food for the sick and convalescent. It has evidently been drawn up with care, and is the work of an experienced hand. We would suggest, however, that in any future edition it would be advantageous, especially where wine and other stimulants are concerned, to substitute the number of ounces for the variable and indefinite quantity of a teacupful or wineglassful. In the receipt for calf-foot jelly we find it stated that "brandy may be substituted for the sherry, or half of each may be used," without any intimation of the quantity of the more potent stimulant which would represent the "half an English pint of sherry" previously ordered. It would also be an improvement if the amount of jelly to which the wine is to be added were stated, as at present it appears to be rather indefinite. The "hints for those who provide for the sick" are excellent, and there is a good index to the book.

The Birmingham Medical Review, June, 1886. Edited by ROBERT SAUNDBY and ARTHUR FOXWELL.—Dr. W. Leah thinks that general paralysis of the insane is a kind of system disease of the brain, and advocates its essential ganglionic origin as opposed to the interstitial view. Dr. Suckling writes on amblyopia due to cortical disease. The various reports on diseases of the digestive system, abdominal and pelvic surgery, surgery, medical pathology, and therapeutics, which have characterised the past few numbers of this Review, deserve to be commended as decided steps in the right direction; the brevity of the notes will suit the scanty leisure of general practitioners.

Vorlesungen über Pharmacologie. By Dr. C. BINZ. Third Part. Berlin: A. Hirschwald. 1886.—This is the concluding part of Dr. Binz's work on Pharmacology. It deals with bismuth, silver, mercury, antiseptics, quinine, salicylic acid, resorcin, kairin, thallin, prussic acid, anthelmintics, fatty oils, glycerine, gums, &c. The work is of the most laborious and exhaustive kind, and is sure to meet with the success it deserves.

New Inventions.

A MIDWIFERY SATCHEL FOR THE SADDLE.

PERHAPS a description of a leather case for midwifery instruments and bottles, which I have recently had made for myself, will be of use to some country practitioners who do most of their work on horseback. The case is made of the best pigskin, and is fifteen inches long by eleven inches in circumference; it is oval at the ends, and is closed by three straps, and attached to the front of the off-side of the saddle by two encircling bands of leather. Its contents are as follows:—One three-ounce bottle of chloroform, two one-ounce bottles containing ergot and turpentine, one half-ounce bottle of Bonjean's solution of ergotin for subcutaneous injection, a small bottle of Savory and Moore's gelatine discs of morphia, hypodermic syringe in case, a pair of probe-pointed scissors, a book of curved needles with stout silk sutures, a Higginson's syringe with vaginal pipe, a gum-elastic catheter, and a pair of Simpson's long forceps. All the instruments and bottles fit in perfectly, and can be taken out for use as quickly as from the ordinary obstetric bag. It is not at all in the way when riding. The case was made for me by Mr. Bowden, saddler, Medbourne, near Market Harborough.

GEORGE D. MACKINTOSH.

Hallaton, Uppingham, July 12th, 1886.

THE LANCET.

LONDON: SATURDAY, JULY 24, 1886.

AN action recently brought by a gentleman in Huddersfield against the Mayor and Corporation of that borough, in their capacity as suppliers of the public water-service, has been three times before a court of law, and has recently terminated in a judgment delivered in the House of Lords, which, for the time being, decides an important question in connexion with the responsibilities attaching to water companies. The case will be known as that of MILNES *v.* the Mayor, &c., of Huddersfield; Mr. MILNES bringing his action against the defendants for injury to his health by reason of lead-poisoning, due to lead contained in the water as supplied to his house from the public service. No question whatever arose as to the fact that some special solvent of lead had acted upon the lead service-pipes and had produced the results in question. But the Corporation denied that they had any responsibility as to any results which were brought about by the service-pipes, their Act of Parliament simply requiring them to lay down pipes in every part of the town, and to deliver by means of these pipes a supply of pure and wholesome water sufficient for the domestic use of all the inhabitants, and to furnish such supply to any inhabitant for his domestic purposes. Their duty ended, they contended, when they kept in their mains such a supply as was specified, and if injury happened to the water after it left the mains, by reason of the use of lead service-pipes or otherwise, the responsibility for any resulting mischief could not rest with them. This view had already been upheld in two courts of law, and against it Mr. MILNES appealed to the House of Lords. Lord SELBORNE and Lord WATSON would have reversed the decision, but the majority of the Court were in favour of upholding it. Indeed, Lord SELBORNE took a common-sense view of the subject a view, however, which in the opinion of the majority of the law lords was not strictly the legal one. He contended that the object of all Water Acts was that the consumers should be supplied with water fit for drinking, and not with a substance that might be poisonous to those consuming it; and also that the Legislature must have contemplated the introduction and supply of water into the houses of the consumers by the usual means—namely, by service-pipes passing from the mains into the interior of the dwellings. And if water could not pass through those various means of supply without becoming poisonous, it could not be regarded as fulfilling the primary objects for which the supply was required. It is true that the legal property in the service-pipes vested in the consumer, but, as Lord SELBORNE stated, this was a matter of but trivial importance unless the consumer was free to decide the material of which they were to be made. But unfortunately the service-pipes under the general Act, though laid down at the cost of the consumer, were to be of a strength "and material approved by the undertakers, and to be laid down under the superintendence of their officers." And so also, by the special Act for Huddersfield, absolute power was given to the Corporation as undertakers to "prescribe the size, nature, strength and materials," &c., of all consumers' pipes. The respondents maintained their rights of control under these Acts, and they exercised the powers vested in them by prescribing lead as the necessary material for the service-pipes; in fact, they themselves supplied and laid down the lead pipes. Under these circumstances Lord SELBORNE maintained that the Corporation had failed to fulfil their statutory obligation affording a wholesome water for the consumers—and this although the water in the public mains was admittedly wholesome and free from lead.

But, as already stated, the majority of the Court held a different opinion. Lord BRAMWELL contended that the water as supplied by the undertakers to the complainant was from the main; that the water as delivered from that main by the Corporation was wholesome, as required; and that if anything went wrong with it afterwards, it was not the fault of the defendants' water, but that of the consumer's pipe. And so it comes to this, that although a water company can under bye-law deprive the inhabitant, at whose expense they carry out the plumber's work, of all discretion as to the materials of which his service-pipes are to be made, yet they may disclaim all responsibility for any untoward results following on their action in this matter. This must now be regarded as being the law on this subject, and the only remaining remedy is to get the law altered.

The Huddersfield case presents, quite apart from its legal aspects, several very interesting phases. The methods by which soft waters occasionally, and at times at long intervals, suddenly acquire the property of taking up lead in quantities sufficing to produce symptoms of plumbism, are still very obscure, but it is probable that in the case of some waters derived from moor-land, the formation of the acids leading to this result may be due to the decomposition, under certain exceptional conditions, of vegetable matters. Several such cases have recently occurred, and we may shortly have an opportunity of referring to this aspect of the question.

SINCE the unusual course followed by the head master of the Charterhouse School in the case of Mr. GARRITT'S son was brought to public notice, a number of letters have appeared on the subject. But although they have cleared up some points, they still leave others in an unsatisfactory state. It appears that the house master of the boy retained him in the house contrary to the wish of the medical officer of the school; but the reason for this seems to have been that the infirmary was already occupied by some cases of measles, and we presume it was considered that less risk would be run by isolating the boy in the master's house than by introducing such a case among the boys in the infirmary. The isolation is stated to have been as complete as it could have been made under the circumstances. One of the masters, Mr. PAGE, has written what he doubtless considers a defence of the school, and so it is as regards some statements which appeared under the signature of "Censor"; but he has not attempted any explanation of the silence of the house master regarding the cases of diphtheria, when he told the boy to write about the existence of measles in the house. Nor has he said anything in defence of Dr. HAIG-BROWN'S decision in

forbidding the return of the boy to the school if taken home from the house in which the cases of diphtheria had occurred, and where one of the convalescents was still resident. The removal of the boy may have been deemed to have arisen from over-anxiety on the part of Mr. CARRITT; but it was surely an over-anxiety which, under all the circumstances, deserved some consideration on the part of the head master.

Until the receipt of Dr. C. HAIG-BROWN'S letter, published in another column, and which arrived as we were going to press, we were left without any satisfactory information as to whether the prevalence of this diphtheritic affection (for we must include under this term the cases also of sore-throat) was confined to one or more houses, or whether it was general over the school; nor has anything been said with regard to an inquiry into its causes and the means to be adopted to prevent its recurrence, beyond the general statement by Mr. PAGE that "the steps which are being already taken with a view to the thorough examination of all the houses and the remedying of any defects will, it is hoped, ensure even greater healthiness in the future." That some such inquiry was much needed is obvious from the remark made by Sir ARTHUR CLAY that "the real trouble is the defective drainage of a portion of the school, and until this is remedied constantly recurring outbreaks of disease may be expected. The question has long been under discussion, but no effective action has been taken."

It is very satisfactory to find that general testimony is borne to the zeal and efficiency of Dr. CLARENCE HAIG-BROWN, the medical officer of the school. But the discussion has given rise to some important questions regarding the position held by the medical officer of a public school, the responsibility which should attach to the appointment, and the power with which he should be invested. It appears that at the Charterhouse School the nomination of the medical officer rests with the masters. This is clearly a mistake; he ought to be entirely independent of them, as he may frequently have occasion to interfere with the arrangements which they have made, and which he may consider likely to prove injurious to the boys. He should be selected for the post by the governors, to them alone should he be responsible for the manner in which he discharges his duties, and to them he should have the power of a direct appeal when his recommendations are neglected or over-ruled by the masters; nay more, we think he should be bound to report every such case. This would have the double advantage of causing him to exercise a judicious caution in making recommendations, while it would at the same time tend to prevent any unjustifiable opposition on the part of the masters. The Council of the Medical Officers of Schools Association has drawn up a code of rules for the prevention of infectious diseases in schools. We are not prepared to say that we think these ought to be adopted in all public schools, but it would be most desirable that the medical officer of each school should draw up a code of rules for the medical service of that one to which he is attached, and that he should obtain the sanction of the governors to its adoption, with instructions to report to them any neglect or refusal to comply with it. We feel that it would be useless to ask for autocratic power to carry out his views with regard to the sanitary arrangements of a school, or any such public establishment; but his position should be clearly independent of the masters, and free from all risk of interference on their part, while he should have it in his power to appeal for support, when he deems it necessary, to the governing body, from whom his appointment should emanate, and to whom alone he ought to be responsible. He should be required to make periodical reports on the health of the boys, and invariably to include remarks on the sanitary condition of the school and of the houses, and suggestions for any alterations or improvements which he may consider advisable from a sanitary point of view in the interests of the boys.

EVERY student of medicine knows, when he is questioned on the subject, that there is no hard-and-fast line between the normal and the abnormal; that physiology runs into pathology. It is a mistake to describe life as a very slight process of inflammation, though in a certain curious fashion it may be so considered. Normal nutrition contains within itself the elements of inflammation, which is, in fact, an exaggerated and perverted condition of healthy tissue and vascular action. Whenever differences in degree are the subject of discussion, there is fertile ground for paradoxical statements.

The transition between healthy mental action and delirium is an almost imperceptible one, as is likewise the gradation between normal movements and abnormal ones. The mind is considerably exercised to understand how it is that involuntary movements should be so near akin to paralysis, or absolute want of movement. This department is perhaps one of the most instructive in the whole range of disease. We may examine it a little more closely. Take a normal ganglion cell of the motor kind in the spinal cord. Contemplate its healthy mode of existence. It responds only to stimuli from a special part of the cortex of the brain or from a certain region of the body, with both of which it is in special relation. Increase its irritability, by any of the numerous means, to a considerable extent, and it will discharge its energy "spontaneously." A lesser grade of irritability will render it liable to be discharged on the slightest provocation. Of course this is an illustration of disease, yet how little it apparently differs from a state of health. Although the phenomenon of "irritable weakness" has long been recognised, yet we are inclined to think that it is still insufficiently acknowledged in practice. Actual diseases of the spinal cord afford abundant illustration of the principle. As an example we may consider the "knee-jerk." There are good grounds for believing that the disappearance of this phenomenon is always preceded by a state of exaggeration, transient no doubt in many instances. Weakness of the heart shows itself much more by an increase in the rate of its action, although one might *a priori* be disposed to think that its debility ought to be manifested in the display of less energy. Strange as it may seem, *a priori* thinking is not far wrong even here, if we do but define what is meant by strength. The strongest man, like the most powerful or healthy nerve cell, is to be gauged by the power of self-control and by the deliberateness of actions. The truly strong man about to perform an act effects his object with the expenditure of the least amount of force necessary under the circumstances. The heart, with its work to do, acts in the same economic manner if it be in a state of

health. In febrile states it wastes its forces, acts more quickly, but with less efficiency. And yet this principle of irritability associated with weakness is not found under all circumstances. We have examples of progressive loss of strength without manifestations of increased action. If we attempt to look for uniformity of method in disease we shall be disappointed, or have to search deeply before we arrive at the uniformity of principle on which nature presumably acts. An inquiry into the mechanism by which weakness goes hand in hand with increase of irritability will reveal that there are really two forces at least at work. In the case of the heart the motor nerve cells are under the control of other nerve centres, debility of which is probably the cause of the excessive number of discharges of the former. Probably a similar explanation holds good for the other examples of "irritable weakness," including most cases of mental derangement.

ON Saturday last a number of medical officers of health in the metropolis accompanied the Ambulance Committee of the Metropolitan Asylums Board to inspect the ambulance arrangements for the removal of cases of small-pox. London is so large, and its sanitary work so divided, that, except for this and similar opportunities given by the Managers, the officers whose primary duty is that of preventing disease, would know but little of the important machinery which is depended upon for the limitation of the spread of infectious maladies.

It is not many years since that Londoners were in the habit of using public street conveyances for the removal of the infectious sick; and even when legislation discouraged this procedure, no other vehicles were available but the somewhat ill-constructed ambulances of the Poor-law authorities. It is true that some of the sanitary authorities, more advanced than their fellows, possessed themselves of special carriages for the removal of infectious persons; but certainly in one instance, if not in others, the inconvenience attending the horsing of these vehicles led to the conveyance being used rather for the purpose of exhibition than for that for which it was at first intended. These difficulties were clearly appreciated by the Royal Commission on Fever and Small-pox Hospitals, who recommended that the ambulances should be under the control of the hospital-providing authority, whose responsibility for the care of the sick should thus begin at the patient's home instead of at the doors of the hospital.

The Managers of the Metropolitan Asylums Board have freely accepted the duty which has been imposed upon them, and have organised a service which is unparalleled for its efficiency, and of which London may well be proud. This duty from force of circumstances is not limited to the removal of sick persons from one part of London to another, but includes the far more difficult task of relieving London of infection from small-pox, and conveying the sufferers to a distance outside the metropolis, where their aggregation is not attended by the unfortunate results which arise from the hospital treatment of such cases in London. If the profession had been told only a few years ago that it was proposed to convey persons in the acute stage of small-pox some twenty miles from their home, the idea would have been scouted as an impossibility; but the Managers have contrived to solve this problem, and to remove patients this long distance, not only to the great advantage of the metropolis but without injury to the sufferers.

The Managers have constructed three ambulance stations in connexion with, or rather adjoining, their eastern, western, and south-eastern hospitals. These stations are entirely distinct from the hospitals near which they are placed, and are, so far as the officers are concerned, under entirely separate management; in each are placed a number of admirably constructed ambulances, in which the sick can be removed with the least possible inconvenience; there are, moreover, coachmen, male attendants, and nurses, who accompany each vehicle whenever requisite. Each station is in telephonic communication with the central office, and this office is also in telephonic communication with the offices of the district authorities, with the different hospitals, both on land and water, and with wharves upon the banks of the river. Absolutely within five or six minutes after information has been received from any of the parochial offices of the need for removal of an infected person, an ambulance is on its way from the nearest station to fetch the sufferer. Should the case be one of small-pox which can be removed outside London, the patient is conveyed to one of the wharves. Of these wharves there are three—one, the Western Wharf, which is just approaching completion, is situated in Fulham; another, the South Wharf, in Southwark; the third, the North Wharf, at Poplar. At each of these points is stationed one of three ambulance steamers, two of which were constructed specially for this service, the third having been altered to fit it for its present use. Two of these steamers, the *Maltese Cross* and the *Albert Victor*, contain accommodation for thirty-two patients each; the third, the *Red Cross*, for thirty patients. The planning of these vessels is so excellent, and the furnishing so complete, that the patient is at once received into a perfect hospital; his journey, so far as any fatigue is concerned, ends from the moment he is placed on board. He immediately comes under the care of a medical man and of nurses, and is fed and tended as carefully as if he were resident in one of the land hospitals. Of his voyage down the river he is not conscious, for the steady passage of the vessel through the water is barely perceptible to anyone lying in the well-arranged wards. Later, he reaches the hospital ships at Long Reach, where he has the best of opportunities for his recovery. We recently described in some detail the construction and ventilation of these vessels, and we have now only to add that the arrangements are now supplemented by their being furnished with the electric light, which is supplied from the shore, by complete laundry and disinfecting appliances in a building which is also on the shore, and near to which is erected a large dwelling for the accommodation of nurses, who are thus able to live in reasonable comfort, without exposing the patients to danger of disturbance from their close proximity to a large number of persons in the more restricted space of the hospital ships.

Under these circumstances the risk to London from small-pox is greatly reduced, and the removal of the sick is accomplished without the least inconvenience or prejudice to the patient's recovery. The greatest credit is due to the Managers for this great public service rendered

to the metropolis. Mr. SCOVELL, the chairman of the Ambulance Committee, may regard with much satisfaction the completion of this difficult task, in which we are glad to be able to report that well-known members of our own profession—Surgeon-General BOSTOCK, Drs. FOWLER, LATHAM, and MILLER—have taken an important part.

THE Report of our Commission on the Pollution of the Thames at the Henley Regatta has attracted considerable attention, and it is very generally admitted that it is an anomaly to prevent by stringent legislation the passage into the Thames of the refuse and excreta from a single house, and at the same time to permit a floating town made up of house-boats and other river craft, to pollute the river day after day by means of all its filth, both liquid and solid. One of the principal reasons which led to special legislation for the river Thames was the fact that London derives the greater portion of its water-supply from the river, and it is obvious that the existing legislation must be imperfect in the extreme if it allows the refuse of some hundreds of people to be cast into the stream, and this simply because the population in question do not happen to live on shore at the time when they cause the pollution referred to. It must also be remembered that legislation in this matter has been made the more stringent because of the special danger attaching to the consumption of a water which has been contaminated by human excreta, and having regard to the fact that the filth cast into the Thames by river boats above Teddington tends to find its way into the vicinity of the intakes of the London water companies, it is the more important that the subject to which we have directed attention should be effectually dealt with.

We are fully aware of the difficulty of asserting without hesitation, as regards any special form of refuse, that it would be capable of producing injurious effects if it ultimately came to be mingled with the water in the public mains; we are as yet ignorant as to the precise form and quantity of filth which is necessary to bring about mischievous results. But it is precisely because of our ignorance in this matter that our regulations dealing with the subject should be exceptionally stringent; and the only safe plan is to regard all excremental refuse as potentially poisonous, and to deal with it accordingly. Recent experience has also taught us the need for especial caution in this matter. The chemist has failed to detect anything wrong with water to which choleraic discharges and filtrates of enteric fever discharges have been added in quantities exceeding those which there is strong reason to believe have led to the production of epidemic disease amongst consumers of water-services which have become accidentally contaminated. And not only so, but in such cases as the severe epidemics of enteric fever at Over Darwen and at Caterham, we have learnt that comparatively small quantities of specifically diseased discharges have, even when mingled with very large bodies of water, conveyed disease on a wide scale. In the Caterham case, for example, a portion of the discharges of a single patient were mingled with so large a quantity of water that the attempt of the company to pump the well dry failed even materially to lower the water level—and this although their machinery was kept at work day and night; and yet the water contained the infective material in sufficient quantity to convey disease to several hundreds of the water consumers. The fact is that in these contagia we are dealing with particulate matter capable, under certain conditions, of rapid development and reproduction, and there is no reason for assuming that these favourable conditions are always absent in the river Thames. Quite the contrary: infected streams have before now led to evils as great as those to which we have referred in connexion with infected reservoirs and deep wells, and for this reason those who are responsible for the state of the Thames in relation to the London water service should see that some measures are taken to deal with the evil which our Commission has brought under notice. Possibly the most appropriate plan would be to bring river craft above, if not also below, Teddington Lock under somewhat similar restrictions as canal boats are now subjected to. Under the principal Act relating to the latter class of boats the Local Government Board have power to make regulations relating, amongst other things, to the "general healthiness and convenience of accommodation of the boat.....for promoting cleanliness....." and "for preventing the spread of infectious diseases" by such boats. Possibly the precise terms of the Act might need modification to meet the case of pleasure-boats on the Thames, but it is by no means unlikely that in the provisions of the Acts as to canal boats, and in the staff of officials which is held to be necessary for their enforcement, the basis for such action as may be needed by way of supplement to the existing powers of the Thames Conservancy may be found.

Annotations.

"Ne quid nimis."

INTERMEDIATE M.B. EXAMINATION AT THE UNIVERSITY OF LONDON.

THE success of the experiment of holding two Pass Preliminary Scientific M.B. Examinations in the year has induced the Senate of the University to move still further in advance, and the official minutes now announce that the Intermediate M.B. will also be held twice a year—viz., in July (as at present) and in January. The first examination in January, which will be for a pass only, will be held in 1888, so that time may be afforded to duly publish the new scheme. We need hardly point out that this change will add greatly to the facilities for taking the M.B. degree, is altogether on the lines we have so constantly urged, and was a necessary sequel to the holding of the earlier examination twice annually. At the same time the Senate resolved on a further alteration, which will again bring the two examinations more closely into accord. As now at the Preliminary Scientific, so after the present year at the Intermediate M.B. in July, the candidate will have to elect between taking the pass and the honours papers, which will be distributed on the same day and hour. In other words, candidates for honours will not have to write the pass papers and must take the risk of failure, whilst those who take the pass papers necessarily exclude themselves from honours. In cases in which candidates elect to write the papers for honours and fall short of that standard, the examiners will exercise a discretion as to recommending them for an ordinary pass. There is a little difficulty in carrying out this change, but we believe it works very satisfactorily at the Preliminary Scientific. In and after 1887 the written

examination will commence on the second Monday in July, and the practical and *viva voce* examinations in the week commencing with the fourth Monday. The written part will therefore be a fortnight earlier than at present.

THE ELECTION OF DIRECT REPRESENTATIVES.

THE new Medical Act says that the manner in which the election of direct representatives of the profession shall be conducted is to depend on regulations to be made by the Privy Council. These regulations are not yet completed, and in the present state of political parties a little time may elapse before they are ready for publication. But we may assume that the Privy Council regulations will only have reference to matters of detail—of time and place, and mode by which the voting-papers may most safely reach their destination, &c. They will leave much to the judgment of the profession, and especially of those members who may aspire to election or be put forward by their brethren. While the Privy Council is considering its regulations and the profession is showing a very wise slowness in nominating its representatives, it is a good time to consider the way in which the election should *not* be conducted. Generally speaking, the method of procedure should differ as far as possible from that of an ordinary parliamentary or municipal election. Canvassing should be discouraged or even prohibited, and all the ordinary arts by which candidates misrepresent the issues at stake, by which they elevate themselves and disparage their opponents, must be considered excluded and unworthy. It is desirable, however, that the profession, by the men it chooses and by the methods it pursues, should give evidence of the wisdom and propriety of the concession of direct representation. *Mutatis mutandis*, the election of the Council of the College of Surgeons might be taken as a guide. The differences are that the voters in the one case will amount to as many thousands as in the other case to hundreds, and that the election to the Medical Council will be by voting-papers sent out by and at the expense of the Branch Council of the particular division of the kingdom to each registered practitioner, and returnable to the medical registrar for that division. Nevertheless, the principles ought to be the same. The absence of all coarse methods of electioneering should be insisted on, and those who resort to them should be left out in the cold altogether. The profession is under no delusion as to the powers of the Medical Council, even refreshed, as it is to be, by direct representatives. It may be trusted to act accordingly.

THE CHOLERA EPIDEMIC IN SOUTHERN EUROPE.

WHILST cholera is still widely prevalent in certain portions of Southern Italy, the epidemic appears during the past few days to have been checked in intensity; and this change has been observed in connexion with a diminution in the temperature, which during the previous week had been exceptionally high and oppressive. During the week ending the 19th inst., there were 52 cases and 27 deaths in the town of Brindisi, 237 cases and 107 deaths at Francavilla Fontana, 115 cases and 49 deaths at Latiano, and, in addition to this, several other places in the province of Brindisi were almost continuously affected. Indeed, the daily number of cases and deaths in the province during the week in question have been as high as 115 and 46 respectively, but latterly they have fallen to about 70 and less than 20. Amongst the other places most affected may be mentioned San Vito Dei Normanni, San Donaci, San Pancrazio, and Oria: also Erchie and Manduria in the province of Lecce. The disease was also announced to have again undergone extension in the province of Bari, but no details of this have come to hand. The outbreak in Francavilla Fontana is the most striking feature of the epidemic up to the present date, this town having suffered, in proportion to its population, more severely than almost any place which has been attacked in the peninsula since 1884, and certainly more severely than Naples during the epidemic in that city two years ago. The disease, too, is more persistently maintained in Francavilla Fontana and in Latiano than in any other portion of the kingdom. In the north of Italy the disease appears to be still limited to Venice and to Codigoro in the province of Ferrara. In Venice the fresh cases and deaths during the week ending June 19th have been 7 and 6 respectively, and in Codigoro they were 39 and 14. Reviewing the progress of cholera in Italy during the past week, it must be admitted that the disease, whilst very severe in the localities affected, has not extended itself on so wide a scale as was to have been expected. And it is possible that if the temperature during the next few weeks does not become excessive, no very serious extension may take place. Italy has suffered severely during two consecutive summers, and the present year may be exhibiting a decline previous to the disappearance of the epidemic. This view receives confirmation from the failure of the disease to make headway in the northern part of the peninsula. On the Austrian coast of the Adriatic cholera is still limited to Trieste and Fiume. The records from both places are somewhat broken, and during the week ending the 19th inst. only 19 cases and 8 deaths have been reported from Trieste, and 21 cases and 10 deaths from Fiume. In the latter place, which was first attacked about the beginning of the fourth week in June, 75 cases and 47 deaths have taken place up to the date to which this week's records extend, and on the 14th inst. it was reported that the population were suffering a good deal from panic, and that a large number of the inhabitants had already left the place. In all the towns and localities affected both in Italy and in Austria the officials are endeavouring to reassure the populations, and in Italy the calm behaviour of the people stands out in striking contrast to that which has heretofore been exhibited, especially in Southern Italy. Sanitary measures of a certain sort are also being carried out, and some immediate good may be expected to result. But hitherto these measures have, in the main, been of a temporary character, and except in so far as the works which have been carried out, or which are in contemplation, in a few large cities such as Naples, are concerned, we have as yet not heard of any substantial progress being made towards the prevention of a similar occurrence in the future.

EARLY OPERATIVE TREATMENT OF MORBUS COXÆ.

THE April Bulletin of the Royal Academy of Medicine of Rome reports the presentation, by Dr. P. Postemski, of three boys with hip-disease. Two cases had been treated by the expectant method—counter-irritation and extension, douching and immobility. Abscesses and sinuses formed, and recovery, with considerable deformity, only occurred after the treatment had been persisted in—in one case for two, in the other for four years. In the third case early excision of the head of the femur was followed by rapid recovery. The operation was performed through a semilunar incision behind the great trochanter. The joint contained purulent serum, and was the seat of fungus synovitis. Only a few erosions were visible on the head of the bone. After removing it, the neck of the femur was rounded and refitted into the acetabulum, previously cleaned out by scraping. Drainage, union by interrupted suture, extension, and sublimate dressings were not disturbed for twenty-nine days, when union by first intention was ascertained. All the dressings were removed on the thirty-fifth day. At the end of eight weeks the patient was able

to walk on crutches, and he could dispense with them when presented to the Academy. The case is unquestionably one of deep interest, but its progress at a later stage must be noted before a correct judgment can be formed. Assuming the issue to be entirely favourable, the advice to excise the head of the bone in the early stage of hip-disease raises grave questions. Granted that the danger of the operation is much less in children than in adults, and that the proportion of recoveries is largest when excision is practised before the joint is completely disorganised, two results of experience are specially noteworthy. A large proportion of hip-joint patients do well under appropriate constitutional and local treatment; and excision of the hip is an operation involving risk to life, without the certainty of a strong and useful limb.

THE "SATURDAY REVIEW" EXCITED.

WE are sorry for the Saturday Reviewer who, having indited an article entitled "The Relation of Insanity to Sin," and finding his essay criticised in our columns, is thrown into such a paroxysm of indignant excitement that he straightway pens another article entitled "A Medical Wiseacre," wherein he makes confusion worse confounded. The amenities of journalism are not best maintained by calling names, and we are a little surprised that any article with such a heading as that just quoted should have escaped the editorial eye in control of a periodical usually well conducted; but let that pass. Our concern is with the objection of the writer, not with his style, albeit that, to quote a famous criticism, certainly "lacks finish." This is how the objection runs: "The proposition which we adduced was that in questions of sin, as in questions of crime, the mere wickedness of the acts done was not in itself good evidence whereon to base the defence of madness, except in so far as it could stand the test of the two questions, 'Did he know that what he was doing was wrong? If he did, could he help doing it?' Upon this the wiseacre in THE LANCET finds himself 'compelled by the facts of the case to join issue, and contend that a man may know he is doing wrong, and do it without obligation or impulse of any sort, and yet be insane.' This so-called 'joinder of issue' is, to carry on the legal metaphor, bad on the face of it. It does not contradict what was said on the other side, and it asserts what nobody ever denied." We must be excused for differing from our censor and suggesting that it not only joins issue, but puts the proposition laid down out of consideration. The *Saturday Review* is discussing the relations of sin and insanity, and the questions set out are those laid down by authority as tests for responsibility in cases of alleged insanity, or in which madness is pleaded in defence of a person doing some act which is classed as criminal. And the two questions propounded as tests are shown to be ridiculous. They will neither stand apart nor together. There is simply nothing more to be said on the subject, because it is nothing to the point whether the man knew what he was doing to be wrong or did not know it, and it is nothing to the point whether, knowing or not knowing the nature of the act he performed, he did it because he could not help it, or, being able to help it, he did it because he chose to do it. The question of sanity or insanity is not to be inferred either from the nature of a deed done or the degree of knowledge, or of independence of the person doing it. The question whether or not a person who has done something, good, bad, or indifferent, must turn upon his state of mind, which is a matter wholly apart from his actions. A mad man may do an act good in itself, or a sane man may do a mad act. Mind and conduct are different and often stand apart, particularly in such mental states as constitute what we call disease. This is the sum of the matter at issue, and we say that our "joinder" was perfectly good in so far as our contemporary was writing on the subject named at the head of the column. If the Saturday Reviewer does not see this he must have unconsciously suppressed a term of his syllogism. Meanwhile what does he mean by the following slightly discordant statements: "It would, in his" (i.e., the medical wiseacre's) "judgment, have been more accurate to specify crime instead of speaking vaguely of sin. Here he is in error. It would have been, not more, but less, accurate to specify crime, because we were not writing about *crime*." Mark this, and then read the following: "Lawyers say, Mad people who do not know what they are doing, or who cannot help doing wrong, shall not be punished. Doctors say, But that is an insufficient definition of madness. No one, except doctors, ever said it was a definition of madness at all. It is a definition of *criminality*, and criminality is a question with which doctors are not in the least concerned." Surely our friend is a little mixed. The article was entitled "The Relation of Insanity to Sin." We suggested that it would have been better to have said crime than sin. He objected that he was "not writing about crime," and now he objects that he was not talking about insanity or madness, but about *criminality!* Where are we? Where is he, or—where ought he to be?

THE CEREBELLUM AND THE OLIVARY BODY.

ONE of the most interesting communications in the current number of the *Journal of Mental Science* is a clinical note by Mr. W. Dudley. The case is that of a man aged sixty-two, in whose *left* cerebellar hemisphere was an area of softening occupying the central part and including the corpus dentatum—the, so to speak, olivary body of the cerebellum. The *right* olivary body presented a gelatinous appearance, and its convoluted grey matter seemed absent. The microscopical examination revealed a great contrast between the olivary bodies. The left one was normal; the grey matter of the right exhibited but few nerve cells, though abundance of coarse granular matter, probably the remains of atrophied cells. No tract of degeneration was detected in the medulla or spinal cord. In the case in question there was considerable difficulty of articulation, which may have been due to the atrophy of the olivary body. The crossed connexion of the cerebellum and olivary bodies appears to be illustrated by this case, for it does not seem likely that the lesions were coincident; nevertheless, there were foci of softening in other parts of the brain.

"CLEVERNESS."

IN early life the thoughtful mind is puzzled by many things difficult to be understood. As thoughtfulness belongs to every normal child, it follows that most of us have been puzzled to explain satisfactorily what is meant by being clever. We all like to be credited with the possession of something that excites admiration, and many a child jumps at anything that will bring him some small measure of notice above his fellows. This trait in the human character is one of a very useful order, but occasionally, like everything else, it carries mischief in its train. Even the most mediocre intellect is occasionally the seat of some sort of cleverness. In certain natures a little praise is a dangerous reward, for flattered vanity works hard for distinctions that do not rightly belong to it. Sometimes vain minds give way to the strain brought upon them by their own inordinate love of being thought "clever." The term "cleverness," as it is now used, must be held to be of most indefinite meaning. How are we to compare the cleverness of different men? The physiologist apparently alone

would be capable of doing this, for he attaches a physiological meaning of some definiteness to every mental act. He might say that the clever pianist had better brain tissue, that allowed of more perfect activity of certain visual centres and the corresponding motor paths by which written music is translated into movements and their attendant sounds. As the brain is a sort of representative parliament, it is easily conceivable how some of the representatives should be more efficient than others. In other words, some parts of human brains are more perfect than others. Some people have "ears" for music, whilst it is notorious that some clever men are unable to appreciate musical sounds.

DRINKING-WATER FOR VESSELS IN THE PORT OF LONDON.

THE supply of pure water to ships is at all times of the greatest importance, and especially so during hot weather. From a report issued by Dr. Collingridge on the subject we learn that many of the dock companies supply shipping direct from the water company's mains by means of hose. In the river, however, and the London, St. Katharine's, East and West India, and Commercial docks, water is carried by means of special barges, which derive their supply from the East London Water Company. Inasmuch as such barges are liable to contamination, it is satisfactory to know that they are under constant inspection by the Port Sanitary Authority, and that thorough cleansing is required at stated intervals. At the Thames Police Court last week the Samaritan Water Company were summoned by an inspector for neglecting such cleansing and repairs, and an order was issued by the magistrate with costs. The Port Sanitary Authority are endeavouring to induce the dock companies to take the supply of water into their own hands, and thus minimise the danger of pollution.

TUBERCULOUS MILK.

A SERIES of researches and experiments in testing milk and its infectious qualities in the case of tuberculous cows has been published in a Scandinavian journal by Drs. Bang and V. Storch. Dr. Bang found that milk both from the tuberculous portion of the udder and the healthy portion contains bacilli, and always produces tuberculosis in rabbits inoculated with it; also that milk from tuberculous cows without diseased udders was not infectious in some cases, but in others it contained bacilli and produced tuberculosis by inoculation. On further investigation it was found that all the animals thus experimented on developed typical artificial tuberculosis. Milk containing bacilli was then put into a centrifugal cream-producing apparatus, and when the vessel was made to revolve most of the bacilli collected in the film adhering to the periphery of the vessel; but the cream itself contained a certain number, and produced tuberculosis by inoculation. Again, the cream, after exposure in a dish for some time, was found to contain bacilli, the acidity having no destructive influence on them. Butter made from such cream was infectious. Heating to a temperature of 60°C. was found to lessen to a great extent the noxious properties; heating to 70°C. in many cases destroyed infection, but not in all. Dr. Storch, in his chemical examination of milk from tuberculous udders, found that that from the diseased portion of the gland had a strong alkaline reaction; at the commencement of the disease it resembled healthy milk in appearance, but in the later stages it was thin, watery, and yellowish-brown; the milk from the healthy portion, on the other hand, was thick and of creamy consistence. In milk from the diseased part an increase of water and albumen was found, whilst there was a decrease of milk, sugar, and fat. From the healthy portion of the same gland the milk was found to be more concentrated, the albumen and water being diminished, whilst the fat, milk, and sugar were increased. The ash obtained from the milk in the sound portion was not abnormal, but in that from the milk in the diseased part a great decrease of calcareous matter was observed and an increase of soda. Dr. Storch endeavours to explain these phenomena by suggesting that probably milk, sugar, and fat are formed in the udder, and albumen and water in the cells of the gland.

THE INTERNATIONAL MEDICAL CONGRESS.

OUR latest information is to the effect that the arrangements for the great International Congress at Washington are progressing favourably. In the case of many of our European brethren the occasion of a visit to the United States will be a unique one in their lives. We have not yet reached that familiarity with the Atlantic which is such an attainment in our American brothers,—

> Qui siccis oculis monstra natantia,
> Qui vidit mare turgidum.

Nevertheless, many on this side are anxious to return the visits so generously made from the other. And whatever the discomforts of the voyage or the severity of the *mal de mer*, we are likely to have the advantage of much brotherly assistance and advice. It may mark a new era in the treatment of sea-sickness, when so many zealous physicians and surgeons are set in competition for their own relief. Be this as it may, great preparations are being made in Washington and elsewhere, and it only remains for Europe to see that the guests are forthcoming. It is the great element in all such gatherings that they be well "furnished with guests," and we would now urge on the profession and its leaders that they will do a great service by an early decision to attend, and still more by an early intimation of it to those concerned. There are American physicians who have visited England annually for thirty or forty years, and on rare occasions perhaps more than once in the year. The late Dr. Flint, whose absence will be acutely felt at Brighton this year and at Washington next, had come of late years to think nothing so refreshing as a run to the old home of his forefathers. Let us reciprocate the compliment on this high occasion, and make the very Atlantic the measure of our desire to cultivate international science and friendship.

SUMMER DIARRHŒA IN THE LARGEST ENGLISH TOWNS.

THE recorded death-rate from diarrhœa in the twenty-eight large English towns dealt with in the Registrar-General's Weekly Return, under the influence of the low temperature during the greater part of June, continued exceptionally low during that month. The warmer weather that set in on the 26th ult., and the remarkably hot period of five days from the 3rd to the 7th inst., however, have caused the usual increase of mortality from this cause. During the seven weeks ending July 3rd, the deaths from diarrhœa in the twenty-eight towns slowly increased from 27 to 86, but rose in the following two weeks to 222 and 411 respectively. Of the latter two numbers, 156 and 315 were recorded in London, which, as is generally the case, is one of the first of the large towns to suffer in this way from the advent of hot weather. It should be remembered that during these epidemics of summer diarrhœa about 82 per cent. of the fatal cases occur among infants under one year of age, and about 14 per cent. among children aged between one and five years, only 4 per cent. of the total cases occurring among children and adults aged over five years. It may be noticed that the mean temperature was below the average on each of the ten days ending with Saturday last (17th inst.), and that therefore the increased

mortality from this cause recorded in the week ending 17th may be mainly attributed to the short hot period that ended on the 7th. In the week ending last Saturday the annual death-rate from diarrhœa averaged 2·4 per 1000 in the twenty-eight towns, but was equal to 4·0 in London, while it did not exceed 1·0 in the twenty-seven provincial towns. No death was attributed to diarrhœa during last week in Brighton, Wolverhampton, Bolton, Huddersfield, or Halifax; the highest rates in the provincial towns being 1·6 in Birmingham and Sunderland, 1·8 in Blackburn, 2·9 in Bradford, and 3·4 in Leicester. In addition to the 411 deaths referred to diarrhœa last week in these twenty-eight large towns, 20 were certified from choleraic diarrhœa, infantile cholera, or English cholera; of these, 17 occurred in London, 1 in Preston, 1 in Bradford, and 1 in Newcastle-upon-Tyne.

CHOLERA SCARES.

IT has come to be the fashion to be "frightened of cholera" just at the commencement of the annual touring season, when the inclination is strong upon us to start instantly for foreign scenes and climes. The hotel-keepers of the United Kingdom (of Scotland in particular) have had cause to be thankful for these cholera scares in recent years; for, beyond question, a great many families were deterred from crossing to the Continent last year and the year before by fear of the fell disease, which seemed to have settled itself in Spain and Italy, and threatened to extend its baneful influence over the surrounding countries, even if it did not fasten its grip on our own shores. Again there is "cholera on the Continent," and once more we are scared. What is the truth about the situation? We take it to be simply this: there is undoubtedly peril of the disease abroad, and, unless there be some urgent necessity for visiting the localities where cholera has shown itself, better far to avoid the danger, slight though it may be, of contracting the malady. The probabilities of infection are always greater for visitors to a place and community where disease exists than for members of the resident population, if the conditions of life be the same. Cholera is chiefly, though not exclusively, communicated through water. It is, therefore, obvious that the water of a district in which cholera exists ought not to be drank. At the same time nothing is worse than to diminish the quantity of fluid consumed in warm weather, or when taking more than the habitual amount of muscular exercise. The débris of tissue waste has to be washed away, and the kidney offers the only legitimate mode of exit. Fluid passed through the skin by perspiration had better be counted as loss for economic purposes. Its *chief* value relates to temperature rather than excretion, and for practical health purposes the aim should be to pass off excreta through the kidney, which is not only never overworked by exosmosis of an unirritating fluid holding solids in a state of extreme dilution, but is itself cleansed by normal "flushing." Pure water is the best of all possible agents for promoting the renal excretion, but to drink water in a cholera-stricken district is to drink death. What, then, is to be done? It has been recommended, and very properly, to boil the water used. It is not enough to heat it, the boiling-point must be actually reached, and to make sure of rendering organic poisons inert the boiling should be continued for some little time. Black tea added, with a dash of lemon-juice, will render the boiled water palatable and serviceable, and then it may be taken freely without fear, and with advantage. Meanwhile, it is not much use taking this precaution if we eat recklessly of dishes compounded by the French or Italian cook with water which has not been boiled. This is too often forgotten. In short, soups and other warm food compounded or cooked with water which has not been raised quite to the boiling-point ought to be refused. The roast and genuinely "boiled," the broiled, and if it be possible as a matter of taste—the baked may be used, but nothing that has not necessarily been heated to 212° F., or above it, should be taken. For the rest, cleanliness, moderation, and the avoidance of over-fatigue or nerve excitation are the best preservatives. It is vain to go abroad for health, and tempt perils of disease. If what is sought can be found in a healthy resort abroad—or even at home,—nothing but a spirit of recklessness could induce anyone to enter a district in which cholera has appeared or in close communication with any locality where it exists.

THE GENERAL HOSPITAL, JERSEY.

WE have already noticed the case of this hospital as affected by the lamented death of the late Dr. Chas. Le Vesconte Godfray. Hitherto the hospital has been served by only one honorary medical officer. It so happens that the last two incumbents were very able men viz., Mr. Jones and Dr. Godfray. But it is rarely well with hospitals, any more than with States, when there is in them but one man. There is a want of life, of healthy rivalry, of comparison and competition, and variety. Besides, it is well to distribute the advantage of hospital work and practice. All these considerations weighed strongly with the profession, who almost unanimously urged the appointment of a proper staff. We regret to say that the hospital committee has not accepted this view, but propose to work the hospital by a very singular arrangement—a paid house-surgeon, an honorary officer, who is to have medical and surgical superintendence of the whole establishment. The committee must have great faith in some one man who is to be equal to all surgical and medical cases. But he is not to be quite his own master. He is to be looked after by a council of five practitioners, with whom he is to confer "in all serious cases and in all serious operations." We never heard of such an arrangement. It seems eminently an illustration of the way how *not* to do it, and it will be a matter of regret, we think, if any practitioners are found to give their sanction to such an unusual and unpractical arrangement.

MORBID GERMS IN WATER.

THE close connexion which often exists between drinking-water and the contagion of various diseases is unfortunately too well known to call for fresh announcement. A multitude of plans for purifying household water prove its general recognition. In all these the directing principle aims at the exclusion of organic matter, the source of chemical changes which nourish the omnipresent elements of infection. With regard to morbific germs themselves, it is more than doubtful if any system of filtration can directly destroy or exclude them. It is true that they may be killed by oxygenation, but the power or duration of this process in domestic filtration can seldom, if ever, be relied upon for the purpose. Yet filters form an effectual check to disease the germs of which are conveyed by water. The object still chiefly to be aimed at is therefore to starve out these injurious atoms by removing their organic pabulum. In reasoning thus, however, we imply that disease germs will only develop in water containing organic material, and not in that which is free from it; nor are we without experimental evidence in support of this view. Among investigations into this subject the most recent is that carried out by Messrs. Crookes, Tidy, and Odling on various London waters. Small quantities of culture fluid containing bacillus anthracis were introduced into household waters of different mineral composition, but free alike from organic impurity. In each case the germ remained active for a short time until pro-

bably its food-supply was used up, and the water was infective when added to a sterilised culture medium. After a few hours it lost this property. Thus it appears to be proved that bacillus anthracis, at all events, does not flourish in pure water, and we may probably regard it as being in this respect a test example of the behaviour of other morbid germs. These facts are encouraging since they show that a wholesome water-supply is possible even for the poorest, filter or none, if that in the mains is good and the domestic cistern is uncontaminated by dust or sewer air.

THE MEDICAL MEMBERS OF PARLIAMENT.

THE result of the recent General Election has proved fatal to the candidature of several members of our profession who occupied seats in the last Parliament, and offered themselves for re-election to the forthcoming one. The following have been unseated after a contest:—Dr. Foster, for Chester; Mr. Mitchell Henry, for one of the Glasgow Divisions; Mr. Vanderbyl, for Portsmouth; and Mr. Pilkington, for Southport. Dr. K. J. O'Doherty, who formerly sat for North Meath, did not offer himself as a candidate, private business in one of the colonies claiming his attention. The following have succeeded in retaining their seats:—Sir Guyer Hunter, for the Central Division of Hackney; Dr. C. Cameron, for the College Division of Glasgow; Mr. J. Dillon, for East Mayo; Mr. R. B. Finlay, for Inverness District; Dr. Farquharson, for West Aberdeenshire; Sir J. Trevor Lawrence, for the Reigate Division of Surrey; Dr. R. Macdonald, for Ross and Cromarty; Mr. C. R. D. Tanner, for Mid Cork; Mr. J. E. Kenny, for South Cork; and Mr. G. B. Clark, for Caithness-shire. All the new medical candidates, four in number, suffered defeat: Surgeon-Major Evatt was unsuccessful at Woolwich, Mr. Lawson Tait at Birmingham, Mr. Willis at Battersea, and Dr. Alfred Carpenter, who last year contested the Reigate Division of Surrey, at North Bristol.

MEASLES AT MARLBOROUGH COLLEGE.

AN outbreak of measles at Marlborough College just at the present time, when Charterhouse School is under discussion, has already led to a critical notice in the public press. We have therefore made inquiry at the College, and learn that the disease was introduced among the pupils by a boy who had evidently contracted measles at home, and who first showed symptoms of it some twelve weeks ago, a fortnight after his return to school. He was at once isolated in the sanatorium; but a fortnight later one more boy developed the disease, and a further fortnight later five more cases occurred, four in the same house as that occupied by the first case and one in the College. All the cases were isolated as soon as the boys sickened, but, as is usual with measles, the disease continued to spread, and during the last sixteen days it has been general throughout the school, from thirty to forty boys being in the sanatorium at one time. Altogether seventy boys have been attacked, and there are now only twelve left who have not suffered previously from this affection, and who are therefore regarded as susceptible. A correspondent of the *Daily Telegraph*, whose son is at Marlborough College, complains that notice had not been sent to him of this appearance of disease. The school authorities have, we are informed, communicated with the parents of boys who were believed to be susceptible, but this was not done until the disease had become generally diffused; and we think in all such cases the parents ought to be informed at once, so that, if they so please, they may remove their sons. There may often be difficulty in determining the exact moment when it is necessary to inform parents of the presence of epidemic disease in a school, but we hold very strongly the opinion that when the isolation of the first case has not prevented the development of others, parents should no longer be kept in ignorance of what is taking place and the risks to which their sons are exposed. There is the double question of risk to the boys themselves and of the risks to their brothers and sisters when they return home, and parents should therefore freely decide for themselves whether their children should remain at school or return home. It is satisfactory to learn that under the care of Dr. Penny no deaths have occurred, and that all the boys who are now ill are progressing favourably.

MICROCOCCUS IN BRONCHO-PNEUMONIA.

SOME researches on the micro-organisms of lobular pneumonia have been made by M. Pipping at the suggestion of Friedländer. In seven cases of fourteen examined, a micrococcus has been detected in variable numbers, having a great resemblance to the pneumococcus. The majority of the organisms were grouped in pairs or in chains. In three cases the oval cocci were surrounded by a very distinct capsule. Many of these capsules contained two or more cocci. These cases were uncomplicated by any acute disease. One was associated with carcinoma of the pylorus; the second with multiple cold abscesses of the hips; and the third with arterio-sclerosis and senile atrophy. The author gives a detailed description of the histology and of the experimental cultivations and inoculations with the pneumonic products of the said three cases. The preliminary inoculations in mice, rabbits, and guinea-pigs have yielded results that are in harmony with those obtained by Friedländer in the case of the coccus of lobar pneumonia. In four other cases of pneumonia of recent date M. Pipping discovered cocci having some resemblance to the pneumococcus, but differing in the absence of a capsule. Attempts at cultivation proved futile in two cases, and in the other two led to the development of several species of bacteria, but of none with a capsule. Seven cases yielded negative results. The author concludes that the encapsuled coccus regarded as special to lobar pneumonia is equally the pathogenic agent of some varieties of broncho-pneumonia.

THE METROPOLITAN IMPROVEMENTS IN SOHO.

IT is always pleasant to think that we may have had a share in bringing about any great public good, and we confess to a feeling of no small satisfaction whenever we pass through the new street or see the recent improvements which the Metropolitan Board of Works has effected in Soho. It is now exactly twelve years since THE LANCET appointed a select commission to inquire into the state of the dwellings of the poor in the metropolis, and our commissioner commenced his work with a description of the state of overcrowding in the district of Soho, one of the most insanitary districts in the metropolis. This account of life in Soho attracted no little attention outside the profession. It was quoted more than once in the House of Commons, then engaged in passing the Artisans and Labourers' Dwellings Acts, and was freely commented upon in the daily and weekly press. We shall therefore hardly be accused of presumption if we claim to have had a considerable share in calling public attention to the necessity of rebuilding this squalid quarter. The Metropolitan Board of Works deserve public thanks for their spirited course of action, and no improvements which have been effected of late years have been more needed or more judiciously carried out. Beginning at Piccadilly-circus, where by the demolition of an island of second-rate houses a magnificent "Place" has been formed, the new Shaftesbury-avenue runs north-east, traversing the worst parts of Soho and demolishing the notorious Dudley-street, and emerges in Oxford-street opposite the termination of Hart-street, where it meets the new road which has been

made from the extreme east of London to that spot. Shaftesbury-avenue in its course has let in much light and air where most they were wanted, and has necessarily brought increased potentiality for health with it. To it there are subsidiary improvements. A fine thoroughfare has replaced Newport-market, and the "Sandringham-buildings" cover the ground previously occupied by a rookery. Then, again, an approach to Oxford-street is being made from Trafalgar-square. One side of St. Martin's-place exists no more, Hemming's-row is among the things that have been, a network of slums behind Leicester-square has been demolished, and very soon the facilities of transit from Trafalgar-square to Oxford-street will be greatly increased. In the train of these welcome improvements come health and architectural beauty, and there is every reason to suppose that the enhanced value of the cleared ground will to a great extent save the ratepayers' pockets. We heartily hope that this may be the case.

THE RECTORIAL ELECTION IN THE UNIVERSITY OF BRUSSELS.

ALTHOUGH it was the turn of the Faculty of Medicine to provide the Rector of the University of Brussels this year, it had been decided, in consequence of disputes which have been for some time past agitating the medical professors, that the legal faculty should take the turn so as to allow time for the air on the medical side to become calmer before the next rectorial election. At the last moment, however, it seems that this apparently most sensible arrangement was broken through, the medical faculty taking its proper turn, M. Depaire receiving 29 votes, M. Crocq 6, and M. Prins 1. *La Presse Médicale Belge* says that there is some mystery about the matter, and cannot understand how the "surprise" had been arranged.

HOSPITAL SATURDAY IN LONDON.

SATURDAY was rather a wet day, but this did not daunt the fair ladies who held the boxes for the street collection. Their cheerful kindness deserves a good reward. What, however, the Saturday movement wants is organisation for a weekly penny from the working men of London. Till that is secured, we shall not have a collection worthy of them or of their obligations to the hospitals. The number of collection boxes used on Saturday was larger than in previous years, and additional means of advertising the fund were made use of by the Committee. Amongst other donations received by the secretary is the sum of £40 5*s.* from the manager of the Coffee Tavern Company, being the day's takings at their tavern at the Indian and Colonial Exhibition. Some jewelry has been forwarded by a lady to be sold, and the proceeds devoted to the fund.

THE CEREBRAL LOBES OF FISHES.

THE cerebral lobes of fishes seem useless so far as the ordinary life of these animals goes. Herr Steiner, of Heidelberg, published at the beginning of the year, an interesting account of the effects of ablation of the cerebral lobes of osseous fishes. M. Vulpian has since re-investigated the subject, and has arrived at substantially the same conclusions as Steiner. A full statement of the experiments may be read in *L'Union Médicale*, No. 93. It is concluded that the "will" of osseous fishes is retained in undiminished force, even after the loss of their cerebral lobes; that not only does voluntary power persist, but also that its voluntary manifestations appear to be identical and indistinguishable from those of fishes whose brains are intact. Moreover, as has long been taught, the visual functions seem to be perfectly performed in the absence of the parts of the brain that correspond to the hemispheres of man. There is "nothing new" in all this. But it is well that investigations should be repeated from time to time in the light of newly-acquired knowledge. The vision and "will" of fishes must be widely different from the similarly designated functions in man; though we may readily grant that the difference is rather in degree than in kind.

SUMMER HOLIDAYS FOR THE POOR.

NOTHING in modern philanthropy is more commendable than the anxiety of the wealthy, as the holiday season comes round, to see that the poor have a holiday too. Our daily contemporaries have found time and space even in the excitement of recent weeks to press the claims of churches and societies which cater for the poor in this matter. We cannot express the value we set on such schemes. To take the poor—children or adults—out of their alleys and courts and drop them in a village or at a farmhouse, among cows, trees, green fields, hay-making, in fresh air, or in sight of the sea, is not only to improve their health, but to give them new faith in God and in God-like people. The selection of a particular institution is a secondary matter. But if anybody wants to double the zest of his own holiday, he will secure the end best by such a contribution as he can, with a little self-sacrifice, afford to one of the many funds to which we refer. Some of these institutions are in great pecuniary want. The Convalescent Home, Hall's-green, Sevenoaks, Weald, Kent, complains "that our beds are not half filled, not having sufficient funds to provide food," &c.

NEURALGIA OF THE PUDIC NERVE.

PROFESSOR ADAMKIEWICZ mentions in the Polish journal *Medycyna* a somewhat rare case of neuralgia affecting the pudic nerve. The neuralgias of the ovary and uterus in women and of the seminal ducts in men are, he says, usually described as neuralgiæ pudendo-hæmorrhoidales, but they have not been well worked out. The present case is interesting because the nerve affected arises from the pelvic plexus. Three years ago the patient began to suffer two months after her second confinement with painful spasm of the urethra whenever she attempted to micturate; sometimes, indeed, this spasm prevented her from voiding her urine. Afterwards the pain spread to the vesical region and became more and more frequent, so that at last the woman was scarcely ever free from it. Every movement of the body and any irritation or excitement increased it, and induced a desire to micturate. Morphia and absolute rest in bed produced some alleviation only. A painful spot was found where the gluteus maximus crosses the tuberosity of the ischium, and another on the inner surface of the ascending ramus of the ischium. The treatment adopted was electrical, the anode of a constant current battery being placed between the tuberosity and the spine of the ischium, and the cathode on the sacrum. After daily applications of a few minutes' duration for three months the patient was completely cured.

HOSPITAL SATURDAY IN BIRMINGHAM.

A MEETING of the General Committee of the Birmingham Hospital Saturday movement was held at the Council House last Wednesday evening. The total of this year's collection, amounting to £6821 17*s.* 11*d.*, was divided, after deducting £334 6*s.* for expenses, and reserving £87 11*s.* 11*d.* Some idea of the substantial help derived from this source by the Birmingham medical charities may be formed from the principal cheques which have been handed over by the Treasurer—to the General Hospital, £2151 8*s.* 4*d.*; to the Queen's Hospital, £1201 14*s.* 5*d.*; the General Dispensary, £715 10*s.* 6*d.*; the Children's Hospital, £577 2*s.* 4*d.*, &c.

TEMPERANCE LEGISLATION.

ATTENTION has been once again drawn to the great evils inflicted on our race and on those who live under its rule, otherwise mainly beneficent, by drunkenness. The question of treatment has already been frequently discussed, and not without result in a large diminution in the prevalence of this fatal habit. The subject, as taken up at the recent Temperance Congress, extends over a wider field, and will bear still further consideration. As to the theory of temperance, our own views are in accord with those most frequently published and with physiological teaching—namely, that alcohol is to be used to satisfy a necessity, not a desire; and that its occasional and sparing use at the table cannot, on scientific grounds, be condemned as if it were an actual poison. We are disposed, accordingly, to discourage the general use of stimulants allowed by custom, and to devote them to the need of persons in weakened health. Discouragement is no doubt a somewhat vague term. From the medical standpoint it is strictly equivalent to dissuasion; but if it is to act as a practical check upon drunkenness, it must, at all events sometimes, mean more than this. Local option and the compulsory restraint of inebriates are methods included in this extended meaning which have been freely discussed by the members of the Congress. It is significant with regard to the latter that restraint of a somewhat vigorous kind has been legally applied for years in many of our most flourishing colonies, apparently with the best effects, and without engendering any of that feeling of injustice which might have followed such a marked coercion of the individual. The hint is not to be neglected. It should do much to influence public opinion at home in favour of a legislative movement in this direction. Those who oppose this benevolent compulsion can hardly plead the liberty of the subject of intoxication. An occasional relapse into drunken indulgence might not, indeed, justify his prolonged detention, but we have to consider further stages of alcoholism. Where the habit is formed, will and business capacity utterly unreliable, and particularly where the well-being of others is being drawn into the vortex of disaster, the drunkard is no longer merely an offender against social rule but an invalid, and restraint implies no tyranny, but is his only means of cure and the safeguard of his family. With due precautions against abuse, we should therefore advocate a measure which would considerably strengthen the imperfect provisions of our Habitual Drunkards Act.

THE DOCTORATE IN BUENOS AYRES.

A CORRESPONDENT of the *Revista Argentina de Ciencias Médicas* complains bitterly of the imperfect and irregular way in which the Buenos Ayres Faculty of Medicine examines the theses presented by candidates for the degree of Doctor. To begin with, it is extremely difficult, says the writer, to get together an examination commission at all, and when this has been accomplished and the candidate presents himself for the purpose of defending his propositions, it may be seen that none of the members of the commission have found time to read even the title-page of the dissertation which the candidate has published. The exercise under these circumstances, if they really are as stated by the writer, can hardly fail to degenerate into a farce.

DAMP TENTS AT WIMBLEDON.

THERE is a good deal to be said for the system which requires that Volunteers while engaged in military manœuvres should "rough it" like soldiers on active service. The Volunteer force is for the time being an army in the field. It is, after all, only practising some of the habits and usages which belong to it as a professional body, and these its members must acquire if they are to be relied upon in case of a national emergency. The rough open-air life of such occasions is fitted to invigorate rather than to weaken men of ordinarily strong physique, and none who cannot be thus described should engage in it. It is different with such gatherings as the Wimbledon Meeting. There is but one work to be done, and that demands for its successful execution a steadiness of head and hand, and a freedom from uneasiness generally, which are incompatible with the inconvenience of a wet-clad life on wet ground, and the frequent rheumatic consequences of such a life. A Volunteer marksman writes to ask that wooden flooring, one of the allowed luxuries of the Common, should be made a regular part of the furniture of all tents in use there at the present time. In the circumstances—a great shooting crisis in uncertain British weather—his request seems only reasonable, if the question as to funds can be satisfactorily answered.

PROPOSED CONJOINT EXAMINING SCHEME FOR IRELAND.

THE joint committee of the Royal College of Surgeons and the College of Physicians, Ireland, have made great progress with the scheme for a conjoint examination between the two Colleges, on the basis of the London Colleges. The fees for the diploma will, it is believed, remain as at present. The Council of the Royal College of Surgeons need not refer the matter to the Fellows for adoption, but will probably submit the scheme when completed to a meeting of the College. The Apothecaries' Hall has been excluded, an arrangement very unwillingly agreed to by the College of Surgeons.

TREATMENT OF THE BITES OF RABID DOGS.

THE chief surgeon to the Metropolitan police, Mr. Mackellar, has issued a circular to the divisional surgeons advising that in cases of bites of dogs reported to be rabid the following treatment should be adopted:—"When possible a ligature to be applied above the part bitten; prompt and thorough suction of the wound, freely washing with water, and the application of absolute phenol (pure carbolic acid). The individual sucking the wound (usually the patient himself) to spit out all the matter so sucked, and to freely wash out the mouth with water. Should the wound be a punctured wound, make a crucial incision, promote and encourage bleeding, and treat as above." The circular adds that the use of nitrate of silver is to be condemned as inefficient, and that the phenol is painful only for a few minutes.

VIEWING REMAINS.

THE most that can possibly be said in favour of keeping up the absurd custom of compelling coroners' juries to "view" the remains of the subjects of inquest is that it is an ancient usage. No conceivable purpose is answered or even assumed, as the object of the inquiry is not to determine the *fact*, but to ascertain the "cause" of the death. If, however, it were necessary that those who serve on juries should be exposed to this disgusting and often dangerous ordeal, there would not be any excuse for increasing the risk incurred by neglect of the most ordinary sanitary precautions. The manner in which this neglect is practised at some of the metropolitan mortuaries would seem to be marvellous. The Home Office ought to be moved in the matter. It is useless remonstrating with local authorities. Better not waste precious time, but go at once to head-quarters to obtain the reform urgently needed.

FOREIGN UNIVERSITIES AND PROFESSORSHIPS.

DR. JOSEPH FORSTER, Professor of Hygiene in Amsterdam, has been elected a member of the Netherlands Academy of Sciences.

The University of Bern has at present both a Medical Rector, Professor Pflüger (Ophthalmology), and a Medical Dean, Professor Kronecker (Physiology).

The Academy of Lausanne, which has hitherto only possessed three medical professorships—viz., Anatomy, Physiology, and Histology, held respectively by Professors Bugnion, Herzen, and Löwenthal,—is now likely to be transformed into a complete university, the means having been furnished by a Russian, who has bequeathed a sum of money to the town for this purpose.

Dr. H. Fol, Professor of Embryology in Geneva, has resigned his post. He has issued a pamphlet explaining the circumstances which have induced him to take this step. The Professor has published various researches on malformations, a human embryo, and notably one on a micro-organism found in the spinal cord of rabid animals.

MEDICAL DOCUMENTS.

THE Medical Council, at their recent session, resolved to form a Library of Reference, to consist of Acts of Parliament, Parliamentary Reports and Bills, edicts, charters, statutes, and calendars, statistical records, books, pamphlets, or documents relating to medical education, examination, qualification, and registration, or to the government of the profession at home or in any foreign country or our own colonies. The Council will gratefully receive and acknowledge any presents of this kind. It is intended that every registered practitioner shall have access to this library.

HYDATID OF THE LUNG PRODUCING NO SYMPTOMS.

A SPECIMEN of hydatid cyst of the lung was shown at a recent meeting of the Paris Anatomical Society by M. Limpéropoulo. It was situated in the parenchyma, and was about the size of a large nut, the wall being thick and containing calcareous granules. No symptom of this foreign body's existence in the lung was observed during life, beyond some chronic bronchitis and emphysema from which the patient suffered. There were, besides, cardiac hypertrophy and interstitial nephritis.

THE DENTAL HOSPITAL.

WE understand that at the recent election at the Dental Hospital of London a gentleman was selected to fill the vacancy on the staff who merely holds the licence in dental surgery of the Royal College of Surgeons, notwithstanding that there was amongst the candidates at least one having in addition the M.R.C.S. and L.R.C.P. As we have always maintained that the dental surgeon should, like his *confrères* the ophthalmic and aural surgeons, be a qualified member of the prosession first and a specialist afterwards, we regret that a departure from this important principle should have occurred at such a prominent teaching centre as the above-named institution.

TUBERCLE BACILLI IN URINE.

BIZZOZERO'S "Archivio per le Scienze Mediche" (vol. x., n. 19, p. 417) contains a memoir by Dr. Marpurgo under the title "Colonies of the Bacilli of Tuberculosis in Urine." The patient was first seen on the 7th January ult. by Professor de Giovanni in Padua, and he diagnosed renal tuberculosis. The urine (sp. gr. 1026, slightly albuminous) contained large numbers of bacilli, corresponding in every particular with those described by Koch as characteristic of tubercle.

VACATION COURSES AT MUNICH.

THE University of Munich announces a series of vacation courses for practitioners, beginning on September 30th and concluding on October 27th. The subjects include histology, pathological anatomy, post-mortems, bacteriology, medical diagnosis, chemical diagnosis, new methods of treatment, clinical microscopy, children's diseases, laryngoscopy, dermatology and syphilis, surgery, bandaging, orthopædics, ophthalmoscopy, midwifery operations, gynæcological operations, vaginal examinations, and hygienic examination methods. Communications may be addressed to Herrn Privat Docent Dr. Stumpf, Sonnenstrasse, No. 16, München.

DIPHTHERIA IN THE MATERNITY WARDS IN MADRID.

THE Spanish medical journals report that the epidemic of diphtheria which is now prevailing in the capital, having proved fatal to a number of children and some adults, has more recently invaded the gynæcological and maternity wards of the clinical hospital of the College of San Carlos, the sanitary arrangements of which are well known to be exceedingly defective. Numbers of the parturient patients are stated to be suffering from angina diphtheritica of a very fatal character, resisting all the most approved methods of treatment.

THE FUNCTION OF THE TONSILS.

DR. R. HINGSTON FOX, in an interesting article on the Functions of the Tonsils in the twentieth volume of the *Journal of Anatomy and Physiology*, expresses the opinion that these glands belong to the digestive and not the respiratory tract, and that their function is to reabsorb certain constituents of the saliva in the intervals of meals which would otherwise be wasted. He thinks that the view of their having an absorbing function is further supported by the strong evidence of the power of the tonsils to absorb morbid poisons directly from the saliva.

ESERINE AND PILOCARPINE FOR GLAUCOMA.

IT has been objected against eserine that it increases the intra-ocular pressure whilst contracting the pupil; pilocarpine, on the other hand, is said to lower the intra-ocular tension. These myotics have been set against one another in the treatment of some cases of glaucoma. Schlegel has made some experiments on the intra-ocular tension, and arrives at the conclusion that the alkaloid of jaborandi also increases the tension.

HOSPITAL SUNDAY FUND.

THE amount received up to the evening of the 22nd inst. was £36,679, being nearly £5000 in excess of the total sum paid into the Fund last year. Collections yet to be paid in will, we trust, show a still greater increase.

REPORTS relative to the health of the British troops in Egypt up to the 18th ult., just received, show that the total number then remaining in hospital at Assouan was 256, and during the week the deaths had been 27, including 20 from sunstroke or heat, 5 from enteric fever, and 1 from dysentery. Ten per cent. of the troops were sick, exclusive of those invalided.

C. SHERRINGTON, M.B. of Cambridge University, and Rolla E. Rouse, M.D. of London University, have proceeded to Italy, at the request of the Royal Society and the Scientific Research Committee of the British Medical Association, to investigate the causes of the present epidemic of cholera.

THE Medical School of Mexico, having only recently lost by death three of its professors, Drs. Velasco, Montes de Oca, and Ortega, has now to deplore the decease of the senior member of its staff, Dr. Rafael Lucio, who has been connected with the school since its resuscitation in 1833. Dr. Lucio enjoyed a large practice, and his opinion was greatly sought after even at long distances from the capital, both by practitioners and patients. *El Observador Médico* says that it will be impossible to fill the place now so unhappily left vacant.

THE INTERNATIONAL RECORD OF CHARITIES AND CORRECTION is the title of a New York monthly publication, the first five numbers of which have reached us. It aims to fill an unoccupied place in the world, no journal of precisely similar character and scope having ever been published. To those interested (and few are not) in the causes and remedy of social evils—poverty, ignorance, disease, vice, and crime—its columns are certain to prove attractive.

THE vacancies in the medical staff of King's College Hospital, occasioned by the resignation of Dr. George Johnson and the death of Mr. Royes Bell, have been filled by the appointment of Norman Dalton, M.D., as Assistant-Physician, and A. Boyce Barrow, M.B., F.R.C.S., as Assistant-Surgeon.

Pharmacology, Therapeutics, and Dietetics.

SICILIAN CORVO WINES. (R. JAMIESON, EDINBURGH.)

THESE wines (white and red) have been recently introduced as rivals to the French clarets, which they much resemble. They are pure natural wines, and are well suited for any cases in which the corresponding French wines are ordered, over which, moreover, they have some distinct advantages. The red wine is a good tonic, slightly astringent, and adapted for cases of atonic dyspepsia. It has a delicate bouquet, and may be taken by itself or diluted with an equal quantity of water. The amount of alcohol is not in excess—in fact, is less than in most ordinary clarets. The white wine is a stronger and richer wine, contains more sugar, and is gently laxative. It might be advantageously ordered in cases in which constipation is present. Altogether we have been very strongly impressed with the excellence of the Corvo wines.

RHUS RADICANS.

Señor Fernando Altarnirando, writing in the Mexican journal *El Observador Medico* on a plant called locally the Guau or the Mala Mujer, the scientific name of which is Rhus Radicans, states that its active principle is of a peculiarly volatile nature, and relates the case of a man who, after collecting and cutting the plant up, complained of chills and a feeling of extreme fatigue, and subsequently developed a rash, at first erythematous and afterwards pustular, affecting chiefly the groins, axillæ, and other parts where the sudoriffic glands are most numerous. The action of the exhalation from the plant could not well have been direct, as the parts chiefly affected were covered with clothes, and so the writer suggests that the active principle must have entered by the respiratory passages, being then carried by the blood to the skin, where its action became manifest. He advises that preparations of the drug should be made from the freshly-cut plant and its juice, and that all the collecting should be done before sunrise. The tincture might be made use of, but the extract must necessarily be inactive—as, indeed, it has proved itself, having been experimented on by Dr. Dominguez. In case of accidental poisoning, such as in the patient mentioned, the indications would be to produce diaphoresis and to maintain the skin in a state of moisture. In order to prevent toxic effects, those who gather or manipulate the plant should be careful not to breathe air which has passed over it, but should keep to windward of it.

ARBUTIN.

Dr. Borisoff of St. Petersburg, having recently examined "the pharmacological action of arbutin, a glucoside obtained from the leaves of Uva ursi," by means of experiments on dogs and frogs, finds that it has a decided diuretic effect, due to stimulation of the epithelium of the Malpighian bodies and urinary tubules of the kidney, and to increased circulation of blood through the kidneys. Though large doses of arbutin exercise a paralysing effect on the brain of the frog, little general disturbance is caused by the drug in warm-blooded animals, even if given in considerable doses. It exercises a distinct antiseptic influence in lessening the formation of pus in cases of purulent inflammation of the bladder and kidney. Dr. Borisoff thinks this drug may be found of much use in practice. He would give larger doses than those which have been suggested by some writers—e.g., M. Levine. He would commence with from one to two grammes (fifteen to thirty grains), given several times a day in powder or dissolved in water. He has made a diligent search through the scientific journals of all nations for the literature of the subject, and has collected no less than forty-three different articles, mostly from German sources, but with a few American and Russian exceptions.

HYPODERMIC INJECTION OF CARBOLIC ACID IN ERYSIPELAS.

In the venereal wards, under the care of Dr. Montes de Oca, in Buenos Ayres, considerable success has been obtained in cases of erysipelas by the injection of a 2 per cent. solution of carbolic acid, as recommended by Hueter, Boeckel, and Sukowenkoff. Care was taken to introduce the carbolic acid as near as possible to the part attacked. In one case where a patient with syphilitic cachexia had been attacked for the second time, six injections, two being given daily, served to limit the affection to the right ear, which was the part affected, and to entirely prevent its spreading further.

PILIGANINE.

M. Laborde recently presented to the Paris Biological Society a note from M. Bardet on the action of piliganine, one of the alkaloids of the piligan. It is stated to be a convulsive poison with a strong emeto-cathartic action. M. Brown-Séquard remarked that it must therefore be an exception to the rule, for all known convulsive poisons were devoid of action on the digestive canal. M. Grimaux explained that the convulsive effects had been obtained from the alkaloid, while the gastro-intestinal effects had been produced by an infusion of the piligan, so that it was not clear that the infusion contained the alkaloid; indeed, it might have contained some other alkaloid belonging to the same plant.

ON

PASTEUR AND PROTECTIVE INOCULATIONS AGAINST ZYMOTIC DISEASE.

BY T. WHITESIDE HIME, A.B., M.B. DUB., &c.

AN address on the above subject was delivered on Thursday, the 8th inst., at the Royal Institution, Albemarle-street. Dr. Hime observed at the commencement of his address that it seemed to him appropriate that the Royal Institution, which was indissolubly connected with the brilliant researches of Davy, Faraday, and Tyndall in physical science, should be selected as the place for the consideration of the no less remarkable discoveries of Pasteur in another field of labour. If this age had been distinguished as one in which the physical forces are being rendered the docile servitors of man's comfort and convenience, it was no less markedly characterised as the age in which some of the deadly foes of human life, and of the lives of animals most valuable to man, had been not only brought to light but subdued. The object of the address was to trace the connexion between the various studies carried out by Pasteur, and show that, intricate as may be the labyrinth leading from his early studies on alcoholic fermentation to his latest and most astonishing investigations as to preventive inoculations against rabies, still there is a thread which guides safely along the difficult

path. The discovery of the anti-rabic inoculation was not his greatest, though it undoubtedly is that which has attracted most attention. This fact was probably due to the horrible fascination associated with rabies, arising partly from the cruel uncertainty as to what may ensue after a bite, partly from the sudden onset when the disease does break out, largely to the terrible fact that practically every person in whom the symptoms of rabies were once developed might be regarded as condemned to death without hope of reprieve. Estimated according to the actual deaths resulting from it, hydrophobia would be a very insignificant disease. The deaths during the thirty-eight years ending 1884 in England numbered 884. During the ten years ending 1860 they were 98, during the next ten years 143, and during the ten years ending 1880 they had increased to 477—a very sensible increase. After a brief biographical notice of Pasteur, who is now in his sixty-fourth year, and was born in Dole, in the east of France, Dr. Hime stated that his earlier works were purely chemical, his studies having been especially devoted to that branch of science. But he was soon engaged in that path of research which he has ever since been following. His anti-rabic inoculations should not be regarded as an isolated discovery unassociated with any kindred one, and altogether without precedent. It was, on the contrary, a logical and natural outcome of his preceding investigations; and there is reason to hope that future discoveries in the same direction will be made. Nor was this method his first or his greatest discovery. Indeed, being a natural induction from earlier work of his, the source from which the anti-rabic method has flowed must be regarded as a greater discovery still. The phenomena of alcoholic fermentation are as old as Adam; yet never until Pasteur had investigated the subject was it known that they are the result of the vital action of the ferment. The meaningless and unscientific theory of action "by contact" had been considered by Berzelius and Mitscherlich a sufficiently satisfactory source from which to derive the process of fermentation; while Liebig considered that the effects (fermentation) were due, not to the physiological action of the plant, but to some mysterious influence exercised by the dead ferment on the fermentable matter. By showing that yeast will grow in a solution of entirely inorganic matter, he proved that the multiplication of the yeast, essential to fermentation, is a purely physiological process, and is not the result of any special function of dead organic matter with which it may be in contact. His studies in this important direction completely annihilated the theory of spontaneous generation occurring in our present age. By delicate experiments, which at the time were wonderfully original, but now are familiar to thousands, he showed that putrefaction and fermentation could be entirely prevented by the exclusion of the microbes (ferments) so abundant in the air, when once the fermentable or putrescible substance had been sterilised. This exclusion is effectually secured by causing the air to filter through cotton-wool before it comes in contact with the organic matter. Having established the necessity for microbic action in such processes as fermentation, Pasteur first utilised this knowledge in treating what may be termed the diseases of vinegar, wine, &c., these being articles of great commercial value in France. He showed that the "turning" of vinegar, which led to the loss of vast quantities of the material and great pecuniary loss, was due to the action of a special ferment, which, absent from good vinegar, was always present in the vinegar which went bad; and further, he showed how it could be destroyed, and that if the vinegar was sterilised of this ferment it would keep good. Much damage was suffered from the "turning" of wine—some becoming bitter, others ropy, &c. Pasteur showed that these morbid conditions were the result of the activity of a ferment, which could be killed by raising the wine to a temperature of 130° to 140°F., the flavour, appearance, and keeping power of the liquid not being in the least deteriorated. The microbes which effect these destructive changes in vinegar, wine, beer, and, as we see in every-day life, in every form of organic matter, are present in the air. The blood and other tissues of the body are capable of providing nutriment to some of them, not to others. Some, when injected into the living blood, even in millions, speedily perish, no trace being found after a few hours. It has been shown, in a very important study by Wyssokowitch [1] that such organisms are not eliminated through the kidneys, as has commonly been supposed, but that the liver and spleen are the organs where they are to be found last. Other organisms, when thus introduced into the blood, find there all the conditions favourable to their growth and multiplication, and they multiply with such incredible rapidity, and penetrate into every region of the body, so that the normal and regular action of the various organs and tissues of the body is interfered with, and we have a condition of disease established. That these organisms are not omnipresent is seen from the common experience that they do not attack, for example, the whole surface of a fermentable substance at once. Putrefaction, which is simply a form of fermentation with disengagement of offensive gases, does not attack the whole surface of a piece of meat, but begins at certain points.

[1] Archiv f. Hygiene, B. i.

The marked similarity between the phenomena noticeable in certain diseases of men and animals and the commonest form of fermentation had long been observed and commented on. Professor Henle, in a remarkable work on Pathology, published in 1841, reviewed these analogous changes, and from purely theoretical grounds drew the conclusion that the cause of such disease must be living organisms. It was from similar reasoning that Dr. Farr applied the term "zymotic" or fermentive to them, a term which had been almost universally adopted. If a minute quantity of yeast be added to (inoculated on) a solution of sugar, and be kept moderately warm, the sugar will gradually disappear, while the yeast will grow, and ultimately it will be found that the whole mass of the fluid has undergone some change which deprives it of the power of fermenting again; to borrow a medical term, it has become "protected" or "refractory" against further inoculation with yeast. When a person is inoculated with small-pox, gradually the whole mass of the body becomes infected, the virus penetrating from the point of inoculation, the temperature rises, and there ensue symptoms of general disturbance; there is multiplication and increase of the quantity of virus introduced; and as the patient gets better, it is found that he has undergone some change which renders him proof against further inoculation with the virus—he is "protected" or "refractory." The enormous growth in the quantity of virus which occurs when, in consequence of the inoculation of the size of a pin's head, there is produced a copious confluent eruption, compels the belief that this increase is due to a real growth of an organism; and the virus can be propagated in this way *ad infinitum*. Now a chemical compound cannot be "growy." A definite quantity of carbon will combine with a certain proportion of oxygen, and then carbonic acid will be produced; but there will be no more carbon in the resulting carbonic acid than was added to the oxygen. The virus, however, has enormously increased, and it will always multiply when inoculated on suitable soil. Inoculation which had been largely practised to acquire protection against severe attacks of small-pox had to be abandoned and forbidden by law, as it led to an increase of the disease throughout the country. Although the inoculated persons had a very mild attack, still they had genuine small-pox, and could infect others with the worst form. About this time Jenner's great discovery was made. This was not that persons who had been infected with cow-pox escaped variola (the dairy folk of Gloucestershire were able to teach him that fact), but the fact that matter taken from a human being suffering from cow-pox might be used for vaccinating another human being without having recourse to the cow, and that, in fact, after the first vaccination the cow was no longer needed, the humanised lymph being as protective as the original. This was Jenner's great discovery. To perpetuate it Pasteur applied the term "vaccin" to the protective material which he had been able to prepare so as to provide against other diseases. The inefficiency of the protection sometimes afforded by vaccination Dr. Hime considered due to the imperfect performance of the operation, and especially to the insufficient quantity of lymph used. The protection acquired by those with four good cicatrices was known to be enormously greater than that of persons with one. And our present knowledge proves that the struggle for existence which the inoculated organisms must undergo may readily lead to their destruction. If there are not a sufficient number, therefore, they cannot multiply and produce the necessary specific infection. It was when investigating fowl cholera that Pasteur first found that a microbe was the specific cause of the disease. He discovered, further, that it could be propagated outside

the fowl's body in sterilised material, and after two generations of such cultures the virus did not lose its specific characters or intensity if each culture was made from the preceding one at short intervals. If a delay of a few days occurred the virus became weaker, and it could then be obtained of various degrees of virulence, some fatally strong, others so attenuated that a bird inoculated with it only had a trifling illness—but, happy discovery, this trifling ailment protected it against subsequent inoculation with the strongest virus. But he further discovered that the virus could be cultivated of each degree of intensity without altering its strength: the weakest could be cultivated as well as the strongest, and that of any intermediate strength equally. If the weakest virus were cultivated by passing through a series of little birds, it again acquired fatal properties. These remarkable discoveries threw an entirely new light on certain phenomena, and additional and invaluable information was derived from his next investigations, which were into the nature of a destructive disease of silkworms, called "Pebrine," which was threatening almost the very existence of the worm in France and elsewhere. He ultimately, after years of investigation, proved that the disease is due to a microbe, and that if the infected eggs be destroyed only healthy worms will be hatched. He showed that the disease could be propagated by eating infected eggs, or by inoculation through scratches, and was hereditary where infected eggs were laid. The selection of infected eggs was an easy thing. Could disease of higher animals and of man be only traced in this way to their specific cause, and be eradicated? The gradual perfecting of methods of research, and the increased knowledge of processes of disease analogous to those of higher animals, gave every reason for hope. England could boast that Pasteur's discoveries were first utilised for the direct benefit of man by an Englishman, Lister's magnificent antiseptic system having been the direct outcome of Pasteur's work. What suffering, how many lives have been saved by the practice of antiseptic surgery as devised by Lister?

(To be concluded.)

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hexham Rural District.—Dr. Maclagan has submitted to this authority his twelfth annual report on the sanitary condition of the Hexam Rural District, and, like its predecessors, that for 1885 gives evidence of the excellent supervision to which the district is subjected. The annual death-rate from 1874 to 1877 was some 20 per 1000, whereas during the past five years it has varied from 15·5 to 16·8. But even this latter rate is properly regarded as one that should be further reduced, and it is especially in the direction of a diminution in the amount of infantile mortality that the improvement should be sought. Dr. Maclagan hence discusses the causes of the needless mortality amongst children, and referring especially to the system of insurance of infants' lives, he points out that the idea that Christian men and women should profit, even in the slightest degree, from the death of their children is nothing less than horrible; and without imputing any criminal intention on the part of parents, he is quite certain that infant insurance leads to great carelessness, perhaps unintentional, in the rearing of their little ones. Another cause of excessive infant death in the district is the use of so-called soothing syrups containing opium.

Sevenoaks Urban and Rural Districts.—Against an average death-rate of 16·4 per 1000 during the past ten years, that for 1885, in the urban district, was only 14·3; and the amount of infectious disease is at its lowest ebb. Not a death from scarlet fever has occurred for four years in the town: and whilst measles was somewhat prevalent, diphtheria and fever caused each one death only. Mr. Butterfield is also able to record progress in sanitary administration, and the fact that the infectious hospital is maintained in readiness for the purposes to which it should be put. In the *rural district* the death-rate reached 16·3 per 1000. Small-pox led to a serious outbreak at Ide Hill; the disease being imported by hop-pickers. In the absence of a hospital, nurses from the Dover Institute were placed in charge of the infected houses, which, for the purposes of the Public Health Act, may be regarded as having constituted temporary infectious hospitals. Much useful sanitary work was accomplished during the year. The authority, however, successfully opposed the extension of the West Kent Water Company's mains into their district, there being an implied engagement that they would themselves make proper provision in this respect. We hope soon to see evidence of the fulfilment of the expressed intention, for the localities in the chalk hills are sadly in need of a proper and sufficient supply.

Tunbridge Rural District.—This, together with the two preceding districts, forms part of the West Kent Combination, for which Mr. Butterfield acts as health officer. The death-rate for 1885 was 17·7 per 1000, this being higher than in previous years, and the mortality included 13 deaths from diphtheria and 7 from measles. The diphtheria commenced by a fatal attack of "diphtheritic croup" at Brenchley, and by Oct. 11th 5 deaths had occurred. The schools were to be opened the next day, but this was ultimately put off till the 19th, when, no fresh cases having occurred, school work was recommenced. But the weather proved stormy and wet, and several children caught colds, which, according to Mr. Butterfield, predisposed them to infection. Anyhow, by the end of the week 5 children had diphtheria, the cases being more widely scattered than they had been hitherto. In all 16 cases and 9 deaths took place in Brenchley alone. Viewing the epidemic as a whole, Mr. Butterfield adverts to the fact that the points of interest to be noted are the persistent nature of the infection, which may lie latent until favouring seasonable influences cause a rapid diffusion of specific germs, the marked effect of contact in schools, and also the ease with which the poison seemed to be transported from place to place by persons apparently uninfected. He also holds it to be probable that a person who has once had diphtheria may continue to redevelop the disease for a considerable time, thus confirming the view which has recently been put forward by Dr. Astley Gresswell.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5929 births and 3426 deaths were registered during the week ending July 17th. The annual death-rate in these towns, which had slowly increased in the preceding four weeks, from 16·8 to 18·4, further rose last week to 19·7. During the thirteen weeks of last quarter the death-rate in these towns averaged only 18·6 per 1000, and was 2·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 12·1 in Brighton, 15·0 in Huddersfield, 13·9 in Hull, and 14·2 in Derby. The rates in the other towns ranged upwards to 21·9 in Newcastle-upon-Tyne, 22·7 in Blackburn, 24·7 in Preston, and 24·8 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding five weeks from 263 to 474, further rose last week, under the influence of the greater mortality from infantile diarrhœa, to 652; they included 411 from diarrhœa, 93 from measles, 50 from whooping-cough, 41 from scarlet fever, 39 from "fever" (principally enteric), 17 from diphtheria, and 1 from small-pox. No death from any of these zymotic diseases was recorded last week either in Wolverhampton or in Halifax; whereas they caused the highest death-rates in Bradford, Blackburn, Leicester, and Preston. The mortality from diarrhœa showed a further general increase; the largest excess occurred in Blackburn, Bradford, Leicester, and London. Measles caused the highest death-rates in Blackburn, Bolton, and Preston; whooping-cough in Preston; scarlet fever in Salford and Oldham; and "fever" in Nottingham, Portsmouth, Plymouth, and Cardiff. The seventeen deaths from diphtheria in the twenty-eight towns included 14 in London. Small-pox caused 1 death among the residents of London and 1 in Liverpool, but not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had declined in the preceding four weeks from 31 to 12, were 13 on Saturday last; 3 cases were admitted to these hospitals during the week, corresponding with the number in the previous week. The

leaths referred to diseases of the respiratory organs in London, which had been 197 and 190 in the preceding two weeks, further declined last week to 167, and were 37 below he corrected average. The causes of 60, or 1·8 per cent., of he deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Hull, Nottingham, Leicester, Portsmouth, and in seven other maller towns. The largest proportions of uncertified deaths were registered in Blackburn, Halifax, and Bristol.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch owns, which had been 20·8 and 19·0 per 1000 in the preceding two weeks, was 19·2 in the week ending July 17th; his rate was 0·5 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 8·2 and 13·9 in Perth and Greenock, to 21·7 in Glasgow and 23·4 in Paisley. The 175 deaths in the eight towns showed an increase of 4 upon the number in the previous week, and included 27 which were referred to diarrhœa, 18 to whooping-cough, 10 o measles, 7 to scarlet fever, 4 to "fever" (typhus, enteric, r simple), 1 to diphtheria, and 1 to small-pox; in all, 68 leaths resulted from these principal zymotic diseases, against 9 and 64 in the preceding two weeks. These 68 deaths were equal to an annual rate of 2·8 per 1000, which was ·0 below the mean rate from the same diseases in the wenty-eight English towns. The fatal cases of whooping-ough, which had been 10 and 17 in the previous two weeks, urther rose last week to 18, of which 14 occurred in Glasgow nd 3 in Edinburgh. The deaths attributed to diarrhœa, which had steadily increased in the preceding five weeks rom 7 to 24, further rose last week to 27, and exceeded the umber returned in the corresponding week of last year by ; they included 14 in Glasgow, 6 in Dundee, and 4 in Paisley. he 10 deaths from measles showed a further slight decline rom the numbers in recent weeks; 5 occurred in Edinurgh, 3 in Leith, and 2 in Glasgow. The 7 fatal cases of carlet fever, including 5 in Glasgow, corresponded with the umber in the previous week. The deaths from "fever" and iphtheria were not numerous, and were below the average. he reported death from small-pox was a death attributed o chicken-pox in Glasgow. The deaths referred to acute iseases of the respiratory organs in the eight towns, which ad declined in the preceding four weeks from 93 to 74, urther fell last week to 73, but exceeded by 2 the number n the corresponding week of last year. The causes of 59, r more than 12 per cent., of the deaths in the eight towns ast week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 22·9 and 23·1 per 1000 in the preceding two weeks, declined o 19·7 in the week ending July 17th. During the thirteen eeks of last quarter the death-rate in the city averaged 5·6; whereas the mean rate during the same period did ot exceed 17·2 in London and 19·7 in Edinburgh. The 133 eaths in Dublin last week showed a decline of 23 from he number in the previous week, and included 11 which ere referred to the principal zymotic diseases, against 2 and 10 in the preceding two weeks; 5 resulted from fever" (typhus, enteric, or simple), 4 from diarrhœa, from scarlet fever, 1 from diphtheria, and not one either rom small-pox, measles, or whooping-cough. These 11 eaths were equal to an annual rate of 1·6 per 1000, the ates from the same diseases being 5·4 in London and ·5 in Edinburgh. The 5 fatal cases of "fever" showed n increase upon the low numbers returned in any recent eeks; and those of diarrhœa corresponded with the umber in the previous week. Seven inquest cases and 8 eaths from violence were registered; and 36 (a marked ecline from recent weekly numbers) were recorded in ublic institutions. The deaths of infants were fewer than n any previous week of this year, while those of elderly ersons showed an increase upon the low number in the revious week. The causes of 13, or nearly 10 per cent., of he deaths registered during the week were not certified.

MORTALITY IN METROPOLITAN SANITARY AREAS.

The recent death-rate in London has been unprecedentedly ow, and averaged only 17·2 per 1000 during the thirteen eeks of last quarter. This rate was not only the lowest on record for London in the second quarter of the year, but was 3·5 per 1000 below the mean rate in the corresponding periods of the ten years 1876-85. The last weekly return of the Registrar-General contains a table which affords the means of comparing the varying rates of mortality that prevailed during last quarter in the several metropolitan sanitary areas; all the deaths that occurred in the various public institutions having been referred to the areas from which the deceased inmates had been admitted. It appears that, after this distribution, whereas the death-rate was so low as 15·6 in the west and north groups of districts, it was 16·8 in the south districts, 18·4 in the east, and 22·2 in the central. If the local death-rates be calculated in still greater detail, it appears that the following sanitary areas showed excessive rates. The death-rate during the thirteen weeks of last quarter was equal to 22·3 in the Strand, 22·4 in St. Giles's, 23·9 in St. George's, Southwark, 24·6 in St. George's-in-the-East, 25·5 in Holborn, and 27·5 in St. Luke's. It is evident, therefore, that, low as the general London rate was during last quarter, there were no less than six sanitary districts in which the mortality was markedly excessive, not only when compared with the abnormally low rates of last quarter, but when put in comparison with ordinary urban death-rates. These six districts include a large proportion of the most over-crowded and insanitary slums of the metropolis, but none the less are their high death-rates a disgrace to London, throwing a grave responsibility upon their sanitary authorities. With reference to the distribution of fatal zymotic disease in London during last quarter, it may be noted that only 9 deaths from small-pox occurred among the residents of London; of these 2 belonged to St. Pancras, 2 to St. George's, Southwark, and 2 to Lambeth. Measles mortality showed the largest excess in Fulham, St. Luke's, Shoreditch, Camberwell, Greenwich, and Plumstead sanitary areas. One of the most noteworthy results of improved sanitary organisation in London in recent years has been the remarkable decline in the mortality from scarlet fever, and during last quarter only 102 deaths from this disease occurred among the residents of London, the corrected average number being 401. It should be pointed out, however, that 50 of these deaths belonged to East London, the greatest mortality occurring in Mile-end Old Town, where the smallest proportion of cases are sent for isolation in the Metropolitan Asylum Hospitals. Enteric fever mortality has shown a still larger decline in recent years than scarlet fever, and this decline is fully as marked in London as in the rest of England and Wales; the mortality from this disease in London last quarter showed the largest excess in the South districts, especially in Camberwell. The 2 fatal cases of typhus belonged to the crowded portions of Marylebone and of St. George's, Southwark. The successful sanitary experience of recent years points conclusively to the fact that the control of zymotic disease is literally in the hands of sanitary authorities, and of the ratepayers who elect them.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the retirement from Her Majesty's Indian Military Forces of the undermentioned officers:—Brigade Surgeon William Henry Morgan, of the Madras Medical Establishment; Brigade Surgeon Henry Robert Lawrence McDougall, M.D., of the Bombay Medical Establishment; Surgeon-Major Henry Elmsley Busteed, M.D., of the Madras Medical Establishment. The following officers have been granted a step of honorary rank on retirement:—Brigade Surgeon William Henry Morgan, of the Madras Medical Establishment, and Brigade Surgeon Henry Robert Lawrence McDougall, M.D., of the Bombay Medical Establishment, to be Deputy Surgeons-General; Surgeon-Major James Kelly, of the Bengal Medical Establishment, and Surgeon-Major Henry Elmsley Busteed, M.D., of the Madras Medical Establishment, to be Brigade Surgeons.

ADMIRALTY. — The following appointments have been made:—Surgeon Francis M. Puddicombe, to the *Asia;* Surgeon William W. Pryor, additional, to the *Indus;* Surgeon Graham E. Kennedy, to the *Medina;* Surgeon John M. M'Donnell, to the *Medway;* Surgeon John G. Webb, to the *Spey;* Surgeon Martin H. Stock, to the *Tees;* and Surgeon Edward A. Spiller, to the Haslar Hospital (temporary).

ARTILLERY VOLUNTEERS.—1st Ayrshire and Galloway:

Surgeon R. B. Erskine is granted the honorary rank of Surgeon-Major.—1st Devonshire: Peter Maury Deas, Gent., M.D., to be Acting Surgeon.

ENGINEER VOLUNTEERS.—1st Cheshire: Surgeon and Honorary Surgeon-Major C. H. Higgins, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.

RIFLE VOLUNTEERS.—1st Dorsetshire: Acting Surgeon C. W. Parkinson to be Surgeon.—1st Volunteer Battalion, the Hampshire Regiment: Surgeon B. N. Earle is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

THE CHARTERHOUSE SCHOOL.

To the Editor of THE LANCET.

SIR,—In consequence of your notice this week, and for the benefit of those amongst your readers who are interested, I think it well to acquaint you with the details of all cases of sore-throat which have occurred at Charterhouse since the present term commenced, on May 14th. They are divisible into three series:—

1. From May 14th to June 10th four cases of sore-throat came before me for treatment; one catarrhal pharyngitis, three subacute tonsillitis, occurring in different houses and attended with no complication.

2. On June 10th I was called upon to see a case in one of the eleven boarding-houses, which I immediately diagnosed as diphtheria. Two days later a second case of undoubted diphtheria (the boy occupying the next cubicle to the first) occurred in the same house; and within two more days I saw eight other sore-throats elsewhere, which had no local manifestation of diphtheria save congestion (i.e., no membrane), but all their owners had albuminuria. The simple fact of sore-throat being associated with albuminuria was sufficiently striking, and the persistence of the albumen for several days with a subfebrile temperature, taken together with the presence of two marked cases of diphtheria in another part of the school, left no room for doubt as to the nature of the eight sore-throats. These occurred in three separate houses—five in one, two in another, and one in a third. As yet no case has developed any of the paralytic phenomena which are apt to supervene upon diphtheria.

3. Since June 14th I have seen nine cases of sore-throat, one being acute tonsillitis, four mild tonsillitis, and four simple pharyngitis. None have been associated with albuminuria, only three with any rise of temperature, and their distribution has not been specially localised.

It is unnecessary for me to state how the cases of diphtheria were managed; this has been clearly enough brought to light by the recent correspondence in *The Times*, notably in the letters of Dr. Bristowe and Mr. Noble Smith. Suffice it to say, that every case occurring between June 10th and 14th was called diphtheria, and the immediate removal of each from the boarding-house recommended; that the heavy responsibility he was taking upon himself was impressed upon each house master concerned; that each was urged to acquaint the friends of his sick pupils with the nature of their illness; and that it was earnestly advised that the general *exeat* on June 26th should be stopped, not on account of measles, but on account of diphtheria.

But I am anxious to explain that I have long discarded the term "diphtheritic sore-throat" as a dissimulation; all sore-throats are diphtheria or not diphtheria. And so deeply am I impressed with the feeling that an exceedingly mild sore-throat may be the means of conveying diphtheria, that at Charterhouse I am in the habit of advising the isolation of every case of sore-throat, whatever its species. Hitherto my powers have been limited to *giving* advice; I am in hopes that the recent stir will secure for the future its acceptance by those few house masters whose wisdom has led them to act in opposition to it.

Inasmuch as the head-master has asked for the services of the Local Government Board, I see no present need for publicly discussing the etiology of the outbreak.

In conclusion, allow me to express, through your columns, my sense of deep gratitude to those medical friends who have felt it necessary to support me by their testimony on the present occasion.—I am, Sir, yours faithfully,

C. HAIG-BROWN, M.D.,
July 18th, 1886. Medical Officer at Charterhouse School.

THE APPROPRIATION OF PATIENTS BY CONSULTANTS.

To the Editor of THE LANCET.

SIR,—I have read with much interest the correspondence in your columns relative to the absorption of patients by consultants. Perhaps you will allow me to state how the matter appears to an experienced patient. To begin with, I absolutely deny that I am in any way the property of the general practitioner who usually attends me. When my digestion goes astray, or my respiratory organs are attacked by the cold, or I think that my kidneys are out of order, I send for him, conduct a joint examination of myself and my secretions with him, and take his medicine. When more serious and obscure ailments seize me I either send for him with a view of settling on the consultant to be resorted to, or I go straight to the consultant and take his advice, afterwards telling my usual attendant what I have been doing and what advice I have received. If I propose a joint consultation between him and the consultant, I usually observe that it vexes him, and that if he goes it is at a sacrifice of time, patience, and, I suppose, money. He has usually said: "Go yourself, and say so-and-so," giving me some technical details and phrases in which he thinks me imperfect. Our relations are affectionate and enduring, but I have never surrendered my liberty of roaming over the whole profession for advice if I consider that my physical interests require it. I cannot understand how any general practitioner in fair practice can find it worth his while to attend a patient to a consultation in the consultant's quarter, unless he happens to live in that quarter himself. As to the cry of graspingness which has been raised on behalf of the general practitioner, my experience is that in London it is far more profitable in the long run to be a general practitioner in a good neighbourhood than a consultant, however, strong his professional position, unless he happens to be a society physician or a crack operator. I happen to have known a good deal of the behind-the-scenes misery of men occupying a position of national, and indeed international, fame, who are being worried and skinned alive by money lenders to keep up a position in hopes of attracting paying patients who never come.

I am, Sir, your obedient servant,

July 21st, 1886. AN EXPERIENCED PATIENT.

THE PREVENTIVE TREATMENT OF SYPHILIS (?)

To the Editor of THE LANCET.

SIR,—The case published by Mr. Jennings in THE LANCET of the 17th inst. is instructive, as showing how very easily a lesion on the penis, due to some other cause, may be mistaken for a hard chancre. In the case reported there can be no doubt that scabies was present. The absence of evidence of that disease in the interdigital clefts is far from being uncommon, even in well-marked instances. In very young children the buttocks are often the parts earliest attacked.

In the second edition of his "Epitome" Tilbury Fox has stated: "Two or three cases of scabies limited to the penis have recently come under our notice." "In two, suppurating buboes were produced by the irritation, and the disease was thought to be syphilitic." "The diagnosis was rendered easy ..... by the absence of any concomitant evidence of syphilis."

The supposed chancre had apparently been destroyed before the case was seen by Sir William Jenner. The diagnosis of syphilis rested, therefore, upon Mr. Jennings. Accepting his version of the facts, Sir William was no doubt justified in suggesting "the free exhibition of mercury internally."

Now for the evidence of syphilis:—

1. The supposed chancre appeared nearly three weeks after suspicious connexion. "The lymphatic glands in both inguinal regions were slightly enlarged. The physical condition of the lesion on the penis led me to consider it a

hard chancre not yet arrived at maturity." I should be glad to know whether the lymphatic glands are usually or ever affected within "three or four days" of the appearance of the sore? and whether a sore in the "immature" stage has ever been known to cause such enlargement? On the other hand, it is common to find glandular enlargement as the result of the intense irritation set up by the *acarus*, and there is no reason why such should not have been the origin of the enlargement in this case.

2. "The internal use of mercury was discontinued after six weeks." Why? The customary period for administering mercury after a suspicious sore is considerably longer than that number of months, and in this case mercury was given "in order to combat the effects of any portion of syphilitic virus already absorbed." However, in spite of this, the patient soon regained his usual health, and "none of the secondary manifestations of syphilis have appeared." Probably the result would have been the same if the treatment had been restricted to the judicious application of sulphur ointment.

The only conclusions I can draw, therefore, are: 1. That the enlargement of the inguinal glands resulted from some irritation other than that of an *immature* syphilitic sore. 2. That the sore was not syphilitic at all, but was merely an extension of the scabies from the "loins, buttocks, or neighbouring parts. 3. That the appearance of the nodule "at the precise spot" where the penis had been abraded was a mere coincidence. 4. That the semi-indurated, raised nodules, with surrounding inflammatory zones, so often seen in scabies, may, when seen in suspicious spots, not infrequently be mistaken for chancres, and may thus subject the patient to the application of a cautery and to a free exhibition of mercurials.

I am, Sir, yours faithfully,

Pall-mall East, July 19th, 1886. ARTHUR HARRIES, M.D.

To the Editor of THE LANCET.

SIR,—In a letter under the above heading in your issue of the 17th inst., Mr. Jennings claims to have succeeded in curing syphilis, but I venture to think that he has failed to prove his contention. On reading his letter, the first question which naturally rises is this, Was the single case on which he bases his opinion really one of syphilis? The diagnosis of this disease from the chancre is a matter of great difficulty, and is often impossible. Although in his case the glands were enlarged, we are not told whether they exhibited the characteristic specific *induration;* while, on the other hand, the irritation of the scabies might have caused them to enlarge temporarily. The absence of other diagnostic signs certainly leaves it a matter of doubt whether he was really dealing with a case of syphilis or not. But if we accept the case as one of syphilis, Mr. Jennings has surely confused the issue by the use of mercury, for it is an accepted fact that if mercury be given in the primary stage, it may abort the secondary symptoms, though sooner or later signs of the syphilis will appear. The patient would require to be kept under observation for years—for a lifetime—if we are to be sure that the syphilis has been cured. Syphilis is not a continuous disease, but is liable to varying periods of activity and quiescence, periods the length of which may be affected by treatment. The primary sore is the local manifestation of a general disease which has existed for several weeks before the appearance of the chancre, so that Mr. Jennings' "prevention of syphilis" would seem in any case to be a misnomer, while the "cure" is open to doubt. The poison having entered the body several weeks before, can it reasonably be expected that the destruction of the chancre will cure the disease? Why should not the enlarged glands be also attacked by the thermo-cautery? Hill applied nitric acid to a torn frænum twelve hours after connexion, and Diday applied caustic to a chancre six hours after its appearance, yet in both secondary symptoms followed. But, after all, the treatment suggested is hardly new, for as far back as 1840 it was proposed to cut out the chancre. I have seen the chancre cut out in several cases, and I have myself removed it more than once, but in all the cases the secondary symptoms followed in due course. Kölliker has reported eight cases where the chancre was early excised, in five of which syphilis followed, and in the remaining three cases we may claim some allowance for errors in diagnosis which are certain to occur even with the most careful observer. This, then, is a more thorough test than Mr. Jennings' solitary case. The removal of the chancre, it has been asserted, modifies the subsequent syphilis, but this, I think, is still *sub judice*.

I trust the advice given in Mr. Jennings' letter will not be extensively acted upon until some more rigid experiment has demonstrated the accuracy of the deductions it contains. Were it widely followed, we should soon have the cautery applied to every venereal sore, and it would cause some patients much unnecessary pain and anxiety, while to others it would impart a feeling of security which subsequent events might prove to have been false.

I am, Sir, yours faithfully,

R. MCKENZIE JOHNSTON, M.D., F.R.C.S.Ed.

Edinburgh, July 20th, 1886.

To the Editor of THE LANCET.

SIR,—I read with interest the notes on "The Preventive Treatment of Syphilis," by Mr. C. E. Jennings, in your issue of July 17th. I have met with five cases presenting signs similar, in so far as regards danger of specific poisoning, to the one he describes. In all of my cases there was a hard elevated nodule on the dorsum of the penis of the consistence of fibro-cartilage, and sufficient pain and inflammation surrounding the new growth to cause the patient to seek advice. The lympathic glands in one or other inguinal region were in every case enlarged and painful on pressure. The nodules in my cases were about the size of split peas, distinctly circumscribed, but thinner at the margins than at the centre, and varied in position from the root of the penis to immediately behind the corona. All of my cases followed doubtful sexual intercourse, the periods of incubation ranging from ten to twenty days. At the time the first case of this description came under my notice I had under observation a case of gonorrhœa in which, as not infrequently happens, a hard thin plate-like body, about one-eighth of an inch in length and rather less in breadth, had developed in two days, and encircled the urethra immediately behind the frænum. The similarity in feeling of the two growths led me to think that probably they were of a similar nature, and that, although the nodule on the dorsum of the penis was due to a poison which had gained admittance into the system during impure intercourse, the virus was not that of syphilis. I accordingly ordered no antisyphilitic remedies. The nodule gradually disappeared, and was not followed by any secondary symptoms. I treated the other cases in a similar manner, with a like result. I am, Sir, yours faithfully,

Llandudno, July 20th, 1886. JAMES CRAIG, M.B.

LIVERPOOL.

(*From our own Correspondent.*)

THREATENED WATER FAMINE.

OWING to the long-continued hot weather, with absence of rain, we are again threatened with a water famine, and, greatly to the inconvenience of the inhabitants, the authorities have recently placed the city upon a half-service, which means that the supply of water is limited to the hours of from 5 A.M. to 5 P.M. Fortunately, a heavy thunderstorm has occurred to-day, and we are likely to have more rain. It is greatly to be hoped that the constant service will soon be renewed.

THE ELECTION OF MR. REGINALD HARRISON.

The news of Mr. Harrison's election to one of the vacant seats on the Council of the Royal College of Surgeons was received with great satisfaction in local medical circles. Admitting freely all the great services which the metropolitan Fellows have rendered to the profession in general and the College in particular, the presence of provincial Fellows on the Council of the latter is an arrangement, the justice of which has long been also admitted; and as Birmingham, Leeds, and Manchester have each for years had a representative, it is felt that it is now high time that Liverpool had also its local representative. Mr. Harrison is still in his prime, and it is hoped has a long and distinguished career before him.

THE GREEK GIPSIES.

A number of Greek gipsies arrived a few days since at the terminus of the Cheshire lines railway, which from its situation is called the Central Station, *en route* for America. But when their condition was known to the managers of the steamer by which they were to have been conveyed, the latter refused to take them. They accordingly "squatted" upon one of the platforms of the station, to the imminent danger of creating, by their dirty habits, an epidemic among themselves, and of subsequently infecting all who had to use the station. Fortunately this peril was averted by the firmness and promptitude of the railway authorities, aided by the Greek consul, who succeeded in finding them accommodation at the Zoological Gardens, Walton—a not inappropriate residence for such very insanitary lodgers.

ENTERTAINMENT AT THE ROYAL INFIRMARY.

On the 16th inst. another of these very pleasing entertainments, which have been more frequent of late, was held at the Royal Infirmary. It consisted of the "Mikado," performed by the members of St. Peter's Cathedral Church choir, led by Miss Harrison, who presided at the piano. A large number of ladies and gentlemen were present, in addition to the patients and nurses, and all greatly appreciated the performance, which was frequently applauded. Considering the monotonous lives led by the patients, nurses, and other officials of the infirmary, these entertainments, which form a pleasing break in the daily round of duty, cannot be too highly commended, and are deserving of every encouragement.

Liverpool, July 21st.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEW FLOATING HOSPITAL FOR THE TYNE.

THE new floating hospital for the Tyne is now nearly complete. It is built from the designs of Mr. W. G. Laws, our city engineer, and it is expected to be launched on Bank Holiday, August the 2nd, when our port sanitary authority hope to be favoured with the presence of the President of the Local Government Board. The structure is unique of its kind, and is admirably adapted for the purposes for which it is intended. It is constructed on ten cylindrical iron pontoons with hemispherical ends. The buoyancy of each pontoon is 53½ tons, so that the floating power of the hospital is equal to 535 tons. The pontoons are 70 feet long and six in diameter, and resemble huge boilers. Upon each pontoon there are seven "saddles," which support a strong framework of iron consisting of longitudinal rolled girders. These girders are braced together by diagonal T iron, and upon them is carried a deck of creasoted timber, which supports a platform. Upon this deck or platform the superstructure of the hospital and its adjuncts are erected. The deck is partly occupied by three main buildings, six smaller structures, and a mortuary. The main buildings are each 65 feet long, 23½ feet wide, and about 20 feet high. These are each divided into two hospital wards, one of which will contain six and the other four beds. They are spacious, light, and airy apartments, having large windows and special means of ventilation. The interior is lined with polished pine in narrow strips. In each ward there is a central shaft through the roof, fitted in Mr. Kite's patent ventilator, for carrying off the vitiated air. Near the floors there is a series of ventilators for the admission of fresh air, and under the floor of each compartment an air space of about 10 inches. Between the surface of the river and the platform is a space of 4 feet. There will be a perfectly free current of air. The rise and fall of the tides, and the currents produced by the spaces between the pontoons, will prevent the possibility of any impurity existing beneath the hospital. Between the two wards of each hospital is an apartment for the nurses. These apartments are fitted with glazed doors on either side, so that the nurses can command a complete view of each ward. There are also entrances from the deck to the different wards. The main buildings are so arranged that they can be completely isolated. The platform is 140 ft. long and 80 ft. wide, and there is ample space in front of the buildings for the recreation of the convalescent patients. The space between the pontoons is 14½ feet from centre to centre. These curious-looking structures have attracted much attention from passengers on the river, and many speculations have been advanced as to the means of launching, but it is stated by those competent to judge that this can be safely and easily accomplished, and that only a gale of wind would prevent the success of the operation. When launched the hospital will be taken to the berth prepared for it at Jarrow.

POISONING CASES IN THE NORTH.

An inquest has been held at Swalwell, county of Durham, upon a child nine months old, who swallowed some flowers of a wayside plant. This unfortunately turned out to be monkshood, and the usual fatal symptoms of poisoning by aconite were observed.

A woman at Newbiggin-by-the-Sea attempted to commit suicide recently by steeping a quantity of matches in coffee and drinking it. The stomach-pump, however, was promptly used by Dr. Cunningham, and with success. I think if it were more generally known that this instrument was likely to be used in all cases of this nature, it would to some extent deter from these mad attempts at self-destruction now so common amongst weak-minded females in the north.

Newcastle-on-Tyne, July 12th.

BELFAST.

(From our own Correspondent.)

BELFAST MEDICAL STUDENTS' ASSOCIATION.

THE inaugural meeting of this Association was held in Queen's College, Belfast, last week, the Rev. President Porter, D.D., in the chair. The object of this Association is to promote the interests of the medical students as regards their professional training. The President of the College said it gave him extreme pleasure to have an opportunity of meeting a number of the medical students, and to find that they had instituted that Association. He was sure, looking at the objects they had before them, they would do a great deal of good, not merely to themselves individually as students, but to the College and the cause of medical education throughout the north of Ireland. He urged them to increase their efforts in order to keep up the *locus standi* of Queen's College; and, in conclusion, said he would do all in his power for the Association, in order to promote the welfare of the students; and he ventured to predict that it would have a wide and prosperous existence in the future. After Dr. O'Neill (President of the Association), Dr. Lindsay, Dr. Byers, and Dr. Esler had spoken, the meeting concluded with a vote of thanks to the President of the College for his kindness in taking the chair. This Association, which owes its origin in great part to the unceasing energy and enthusiasm of Dr. Henry O'Neill, will be of immense benefit to the medical students in the future, and the kindly interest taken in it by the President has done much to ensure its success.

ANNUAL MEETINGS OF THE MEDICAL SOCIETIES.

The annual meeting of the North of Ireland Branch of the British Medical Association was held in the Royal Hospital on Thursday, July 8th; the principal business being the election of office-bearers for the ensuing year. Mr. John Fagan was appointed president, and Dr. Moore secretary (in place of Dr. Dempsey, who has resigned). In the evening the members dined at the Royal Avenue Hotel, the President in the chair, when those present had a very agreeable reunion. On the previous day, at the annual meeting of the Ulster Medical Society, Dr. Whitla was elected president, Dr. Lindsay secretary, and Dr. Coates treasurer for the coming year.

THE ROYAL HOSPITAL.

The summer session came to a conclusion last week, and most of the students have now left town. During the past two months the surgeons have had a very busy and anxious time. Owing to the unfortunate riots in June, and again last week, a large number of serious gunshot wounds have been admitted to the wards; while, in connexion with the terrible railway accident near Portadown, a good many cases of severe injury were brought to the Royal Hospital. Among these there were cases of head and abdominal injury, affections of joints, simple and compound fractures, &c.

There has been a change in the resident staff owing to the resignation of Dr. S. Smith, house-physician. Dr. Calwell was appointed in his place, and Dr. Shuldham Dunlop has taken the post of house-surgeon—viz., Dr. Calwell. The students attending the hospital presented Dr. Smith with a handsome clock, barometer, and a set of bronzes.

DEATH OF DR. M'WHA.

I am sorry to have to announce the death of Dr. W. R. B. M'Wha. He had obtained an appointment as medical officer in connexion with a tea plantation in India, and had been there only a few days when the unfortunate event occurred. Little is as yet known of the circumstances, as a telegram received in Belfast simply stated that he was drowned while out shooting. Dr. M'Wha was most popular both at school and at College, and being a man of considerable ability and good professional training, his friends looked forward to his having a distinguished professional career. The deceased gentleman was a splendid athlete. As a football player he had few superiors in Belfast, as was shown when he played for Ireland against England, Scotland, and Wales. He was also a member of the Irish lacrosse team. Previously to receiving his appointment in India Dr. M'Wha was one of the resident surgeons in the Union Infirmary. Great sympathy is felt for his bereaved relatives.

THE BELFAST HOSPITAL FOR SKIN DISEASES.

The annual report presented at the last meeting of this institution shows that during the past year 1005 patients were treated at the hospital, thirty-one of whom were in-patients; and that there has been a steady increase in the number of patients since the foundation of the hospital in 1865. Since this date 19,318 cases of skin disease have been treated. The receipts from all sources during the year were £322 9s. 7d., and the expenditure £316 19s. 4d., leaving a small balance to the credit of the institution.

Belfast, July 19th.

PARIS.

(From our own Correspondent.)

PROTEST AGAINST VIVISECTION.

THE *Official Journal* has published the resolution of the Committee appointed by the Chamber of Deputies to report on a petition forwarded by Dr. Combet of Lyons, in which the petitioner states that experiments on living animals as a simple means of instruction is a cruel practice, and absolutely useless, in which opinion he is supported by several professors of the Faculty. He therefore demands that a law be passed to interdict in the faculties and schools of medicine the practice of vivisection and operations for study on living animals. The Commission believed that there might be too many operations of vivisection performed without any practical utility, and that therefore it would be better to put a stop to some of the abuses of unnecessary cruelty. The Commission, however, cannot admit, with the petitioner, that these experiments are altogether useless to the progress of science. Consequently the Commission is of opinion that the operations of vivisection should be restricted to cases determined only by the necessities of science.

THE TREATMENT OF NEPHRITIS.

It is admitted in practice that nephritis in patients suffering from scarlet fever is not always in relation to the gravity of the eruptive disease. Prof. Jaccoud, following the example of Dr. Musatti, who established the fact that milk diet, instituted at the commencement of the malady, is the best remedy to prevent renal complications, employed the same treatment with great success. According to certain authors, renal albuminuria resulting from scarlet fever is very prevalent in some epidemics, and the number of cases so affected has been known to mount up to 50 per cent.—that is, including both slight and grave cases; but Professor Jaccoud, since adopting this method, has never had a single case of renal albuminuria. According to him, the real prophylactic treatment of this complication consists in the administration of milk from the first day of the malady, without waiting for the appearance of albumen in the urine. Milk alone should be given, both as food and medicine—three litres per day if possible. Dr. Musatti condemns the use of the cold bath in scarlet fever, not only on account of the difficulties attending this mode of treatment, but also from the collapse and other complications that may be produced.

APPOINTMENTS.

The vacancy caused by the death of Dr. Legrand du Saulle at the Infirmary for the Insane at the Prefecture of Police has been filled by Dr. Paul Garnier, who had discharged the functions of first assistant at the infirmary.

Dr. Bouchard, Professor of General Pathology and Therapeutics at the Paris Faculty of Medicine, has been elected, almost unanimously, member of the Academy of Medicine in the section of Medical Pathology, having as competitors Drs. Damaschino and Dieulafoy.

ERRATUM.—In the last line of the Paris letter of last week, the word "death" should be *depth*.

Paris, July 20th.

THE FOREIGN HOSPITALS AT CONSTANTINOPLE.

(From a Correspondent.)

THE Constantinople correspondent of the *Journal des Débats* has been contributing a series of letters about the hospitals belonging to the different foreign Powers in that city. There are seven of them in all—viz., the Austro-Hungarian, the English, the French, the German, the Greek, the Italian, and the Russian; and a brief description of each, taken in alphabetical order, will be read with interest.

The Austro-Hungarian hospital, the only foreign one upon the southern side of Pera, has not a building of its own, but rents for about £380 a year a large three-storeyed house with a fine view of the Golden Horn and Stamboul. This hospital has forty-seven beds and five private rooms for female patients. The patients who can afford to pay are charged 3s. a day, and the expenses for the past year amounted to £1200, the difference between the amount received and the total cost being made up by a tax of 2½d. per ton paid by all Austro-Hungarian vessels which come to Constantinople, and in return for which the sailors are treated free of charge. The number of patients who passed through the hospital last year was 208 men and 29 women, the proportion of deaths being 43, or 5·48 per cent. Four attendants (three male and one female) are attached to the hospital; and there is a resident physician, with a salary of £160 per annum.

The English maritime hospital at Galata is a substantial building with two storeys, and though erected at the time of the Crimean war it looks as good as new. There is an indescribable air of comfort about it, and the bedding is exceptionally good, while there is an abundance of water in the building, with baths and washhouses upon the ground-floor, an apparatus for rescuing the patients in the event of fire upon the second storey, and two very ingenious contrivances for ensuring that the medicine has been given at the proper hour. The cost of maintenance and of the linen is borne by the Turkish Ministry of Public Works, while a charge of a penny per ton on the 2000 English vessels which enter the port every year more than covers the rest of the expenditure. There are only two private rooms in the hospital, the occupants of which pay 4s. a day, but all the other patients are treated gratuitously. The hospital contains sixty beds, distributed over six wards, and only male patients are admitted, the total for last year being 238, of whom only 6, or 3 per cent., died. The cost of each patient is estimated at 5s. a day, and the ordinary meals consist of tea and bread-and-butter in the morning and at 4 o'clock; soup and meat at noon, and again at 6 in the evening. There were 526 out-patients last year. Two doctors are attached to the hospital, one of whom is resident; while there are three trained nurses, one of whom learnt her business in a London hospital.

There are two French hospitals at Constantinople, though one of them, the municipal hospital, is so far Turkish that it is kept up by the municipality of Constantinople. It is, however, under the care of six French Sisters of Mercy, who, with very slender resources, manage to maintain forty beds. The total number of patients last year in this hospital, which is situated at Top-Hané, was 902, and the deaths amounted to 63, or rather more than 7 per cent., the high rate of mortality being attributed to the neglect of the Turkish authorities to keep the building in proper order or supply the necessaries for the patients. The Hôpital de la

Paix, situate at Chichli, in the suburbs of the city, is also under the care of Sisters of St. Vincent de Paul, and it dates from the time of the Crimean war, when the Sultan gave them a large piece of land and a sum of £2000, with which they founded a hospital, and also received a few insane persons. They have since been able to build a separate asylum for the insane. The hospital as it now is consists of a large building with two wings, and contains 44 male and 28 female patients of all nationalities; these being divided into four classes, who pay at the rate of £8, £6, £4½, and £3 (Turkish) per month. Annexed to this hospital is a pavilion with twenty beds for male and ten for female patients, and special wards for ophthalmic complaints, the occupants of which pay from 10*s.* to 2*s.* 6*d.* a day. There is also an orphanage and a crèche attached to this hospital, containing 130 children; and the Sisters of St. Vincent de Paul also have charge of the almshouses for the aged, which are placed under the protection of all the Catholic Powers, each of which in turn takes over the management of it for a twelvemonth. These almshouses were founded just half a century ago, and they consist of forty-two cottages, each with two rooms, and now accommodating fifty-five men and twenty-five women. The expenses for last year were £1400, and of this about half is defrayed by the rent of shops upon the ground floor of the houses which face the street. The remainder is made up by grants of charitable societies, and by contributions from a few of the inmates who can afford to pay something towards their maintenance.

The German hospital is the one which costs the least to the Government, as very few except paying patients are received there. The establishment of this hospital dates from 1844, when, at the funeral of a German subject who had died at Constantinople through having failed to secure medical relief, a collection was made for the construction of a small wooden hospital. A few years later a charitable association was founded by the Germans; but it was not until 1875 that the present hospital was built at Taxim, upon the heights of Pera, the money for its erection (about £18,000) being provided by the German Government. The situation of this hospital, which commands a view of the coast of Asia Minor, the Sea of Marmora, and part of Stamboul, of itself contributes, to use the expression of Dr. Mordtmann, one of the physicians attached to it, "to hasten the recovery of our patients." The hospital has four storeys and is surrounded by large gardens, while it has accommodation for a hundred patients in six wards and twenty separate rooms, the charge being from 3*s.* to 5*s.* a day. There is also a pavilion, built of wood, for the patients suffering from contagious diseases, and this was provided by Prince von Reuss, formerly German ambassador at Constantinople. Three doctors and three deaconesses are attached to the hospital, which last year received 620 patients of fifteen different nationalities, the deaths numbering 48, or about 8 per cent. The average daily cost of each patient was about 2*s.*

The Greek hospital at Balukle, outside Stamboul, is nearly a mile from the city, and though from a sanitary point of view its situation is good, the distance tells against it very much in certain cases. It is the largest of all the foreign hospitals, comprising four separate establishments—the hospital properly so called, the asylum for the insane, the orphanage, and the almshouses for the old and the infirm. Founded in 1837, the hospital has been gradually enlarged, and is now administered by a committee of twelve Greek merchants residing at Constantinople. A committee of five ladies has the management of the kitchens, still-rooms, and washhouses, and the hospital has accommodation for 350 patients, who occupy seven wards and six private rooms, in the latter of which the charge for treatment is about 4*s.* a day. There is a very good pharmacy, at which drugs are supplied to out-patients at cost price, and the staff consists of two resident physicians, two visiting physicians, seventy-two attendants, nurses, &c. In the course of last year the hospital received 2481 male and 238 female patients, this being exclusive of those treated in the lunatic asylum, the orphanage, and the almshouses; but the deaths numbered 442, or over 15 per cent. This high rate of mortality is attributed to the fact that a great number of the patients were suffering from fever and other malignant affections, and that the Greeks have such a prejudice against hospitals that they will not make use of them save at the last extremity. Although the Turkish Government allows the hospital 1 cwt. of meat and 1½ cwt. of bread per day, the expenses for the past year, including a sum of £2000 for paying off the building debt, amounted to over £14,000, but the different resources which the committee command enable them to meet this expenditure without much difficulty.

The Italian hospital, which dates from 1876, is situated upon the eminence of Top-Hané, overlooking the sea, and it is a two-storey building with a large garden, having more the appearance of a private villa than of a hospital, and cost about £12,000. It has upon the first floor a ward with ten beds for women and three private rooms; upon the second floor, a ward with twenty beds for men and five private rooms, in addition to a ward with twelve beds for persons suffering from syphilitic complaints. There is a lift for each floor, with waterclosets and dressing-rooms, while the building is well ventilated, and has an abundant supply of soft and salt water. The staff consists of two doctors, four attendants, and fourteen Sisters of the Immaculate Conception. About ten free consultations are given every day, and the other patients pay about 5*s.* if received in private rooms, and half that sum in the wards, foreigners being charged about a quarter more. The hospital received last year 309 male and 41 female patients, the number of deaths being 28, or about 8 per cent.; and the average daily cost per patient was rather more than 1*s.* 6*d.* The paying patients contributed about £400 to the total expenditure, the remainder being defrayed by the Italian Minister of Foreign Affairs.

The last of the seven foreign hospitals is that of Russia, the foundation of which is somewhat remarkable. An Armenian living at Constantinople, but a Russian subject, had supplied the Turkish armies with forage during the Crimean War, and had failed to obtain payment. General Ignatieff, when Russian ambassador at Constantinople, obtained payment for his claim upon condition that he subscribed a quarter of the amount received towards the building of a Russian hospital. This the Armenian, who as a Russian subject had no business to supply the enemy, readily agreed to, and the £8000 which he paid over to General Ignatieff went towards the erection of the large hospital with three floors, and a wooden pavilion for use in the summer, which Russian subjects can now avail themselves of at Constantinople. The hospital is a very wealthy one, for the late Czar made it a donation of 100,000 roubles, and one of the princesses of the Imperial family gave linen for forty beds. The hospital also receives a sum of 1*d.* per ton upon all Russian vessels coming to Constantinople, and the fees upon the issue of all passports. It contains five wards of from three to twelve beds, each patient paying at the rate of 4*s.* a day. It is very well fitted up, with double windows and baths upon each floor, but the temperature is rather too high. No persons suffering from contagious or mental diseases are received. The staff consists of a resident physician and six Sisters of Charity. In the course of last year the number of patients was 283, the deaths numbering 23, or 8·50 per cent.

Among the French hospitals might also have been included the establishment known as the Hôpital Gérémie, but it was at first more of a convalescent home than a hospital in the strict sense of the term, the money for endowing it having been bequeathed about thirteen years ago by M. Gérémie, who left special directions as to how the money was to be employed. Since then it has been converted into a general hospital, and is now open to paying patients of all creeds, having received last year 141 male and 71 female patients, the rate of mortality being 8 per cent. The hospital is situated upon the heights of Ainali-Tchesmé, and has five wards each with eight beds, and five private rooms, or thirty-two beds in all. The hospital is under the charge of the Lazarists of St. Benedict, and has a staff of four physicians, who give their services gratuitously. There is also the civil and maritime French hospital at Taxim, which, though admirably administered internally by the nineteen Sisters of St. Vincent de Paul and the twelve nurses attached to it, is in a very dilapidated condition outside, and is so short of funds that it has only one doctor for eighty-six beds. Still, the French have, upon the whole, more charitable establishments than any other nation at Constantinople, for there is a girls' school and a dispensary attached to the Taxim hospital, while the two homes of Our Lady of Providence and Tchehun-Boslon, both conducted by the Sisters of St. Vincent de Paul, relieved during the past year 1500 men and 1300 women of different nationalities.

(To be continued.)

Obituary.

JAMES ALEXANDER EAMES, M.D.

WITH considerable regret we record the death of a respected member of the profession, which took place on the 17th inst. Dr. Eames was the resident medical superintendent of the Cork District Lunatic Asylum. A few weeks since he was attacked with a cervical anthrax, and although from the first his illness was serious and painful, his medical advisers—Dr. Hobart, Dr. E. Townsend, and Deputy Inspector-General Eames—had a favourable opinion, and believed he would recover. On the morning of Friday, the 16th inst., however, he relapsed, and died the following day. Dr. Eames studied at the Meath Hospital, Dublin, and at the medical school of the Royal College of Surgeons, and acted as an assistant-surgeon in the Crimean war, for which he held a medal and clasp and the Turkish medal. He afterwards devoted his entire attention to the study of mental diseases, and after some time was appointed resident medical superintendent of Donegal Lunatic Asylum. On the death of Dr. Power, of the Cork Asylum, about thirteen years since, Dr. Eames, mainly through the influence of the Duke of Cambridge, whom he attended when wounded in the Crimea, was elected to the vacancy, and the chief improvements in that asylum are to be attributed to Dr. Eames, whose untimely decease will be a great loss to the institution. He was president of the Medico-Psychological Association, honorary member of the Société Médicale Mentale de Belgique, and lecturer on Psychological Medicine in Queen's College, Cork. The deceased was a Fellow of the Royal College of Surgeons in Ireland. Among his surgical contributions to medical literature may be mentioned the following: "Successful Removal of entire Penis and Scrotum;" "Case of Trephining, Recovery;" "Rare and Complicated Luxation of Ankle-joint without Fracture of either Malleolus." Dr. Eames's death will be regretted by a large circle of friends.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on July 19th:

Bewley, Thomas Theodore, M.B. Trin. Coll. Dub., Booterstown.
Brazil, Walter Henry, L.S.A., Bolton.
Drinkwater, Charles, L.S.A., Mildmay-park.
Finley, Frederick Gault, M.D. McGill, Montreal.
Fraser, Nutting Stewart, M.B. Edin., St. John's, Newfoundland.
Gregory, Alfred John, L.S.A., St. John's.
Kennard, Charles Poole, M.B. Edin., Highworth.
Morris, Edward, L.S.A., West Kensington-park.
O'Connor, Charles Patrick, M.B. Durh., March.
Rawnsley, Gerald Thomas, L.S.A., Russell-square.
Smith, John William, M.B. Edin., Lancaster.
Sugden, Edward Scott, M.B. Durh., Battersea-park-road.
Vost, William, M.B. Glasg., Glasgow.

Admitted on the 20th inst.:—

Coad, John Edwin, M.B. Durh., York.
Dawson, Rankine, M.D. McGill, St. George's Club.
Edwards, Percy, L.S.A., Grafton-street West.
Fenton, Charles Francis, L.R.C.P. Lond., Romford.
Hackett, Harry Eugene, L.R.C.P. Lond., Manchester.
Jardine, Robert, M.B. Edin., New Brunswick.
Jones, Thomas Joseph, M.B. Edin., Ross, Herefordshire.
Lister, Joseph Jackson, L.S.A., Leytonstone.
Marquis, Duncan, M.B. Glasg., Marchmont-street.
Ruddock, William James, M.B. Durh., Newcastle-on-Tyne.
Sutherland, George Alexander, M.B. Edin., Aberdeen.
Taylor, Lot Albert, Birmingham.
White, Francis Silva, L.S.A., Lexham-gardens.

Admitted on the 20th inst.:—

Brice, Frederick Augustus, L.S.A., Paignton.
Deane, Edward, L.R.C.P. Lond., Trinity-square.
Duke, Allan Forrester, Folkestone.
Elliott, William Henry Wilson, L.S.A., Chislehurst.
Gault, Arthur Henry, L.R.C.P. Lond., Stockport.
Grayfoot, Blenmar Buhôt, L.R.C.P. Edin., Barbadoes.
Hentsch, George Frederick, L.R.C.P. Lond., Bedford-row.
Holt, Maurice Percy, L.S.A., Putney.
Lindow, Albert, L.S.A., Wolverton.
Manning, Philip Percy, M.B. Durh., Hammersmith.
Penton, R. Hugh, L.R.C.P. Lond., King's County, co. Dublin.
Pocock, Herbert Innes, L.R.C.P. Lond., Bristol.
Vincent, John Francis, L.R.C.P. Lond., Melbourne.

The library and museum will be closed on Tuesday and Wednesday, the 27th and 28th inst., for the purposes of the First Examination of the Examining Board in England.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 15th inst.:—

Brice, Frederick Augustus, Croft Lodge, Paignton, S. Devon.
Compton, William H., Brighton-road, Avenue, Southampton.
Hicks, Edward Harman, Connaught-road, Folkestone.
Holt, Maurice Percy Cue, Upper Parkfield, Putney.
Jones, John Owen, Malvern House, Dolgelly.
Jones, Sydney Harold, George-street, Hanover-square.
Lindow, Albert, Woberton, Bucks.
Payne, W. Arthur, M.R.C.S., Pentre, Uchaf, Oswestry.
Solly, Ernest, Heathfield, Congleton.

THE Library of the Royal Medical and Chirurgical Society will be closed during the month of August.

SIR A. R. THOMPSON, Lieut.-Governor of Bengal, laid the foundation-stone of the Ezra Hospital at Calcutta this week.

THE Drapers' Company have voted 100 guineas towards the building fund of the Tottenham Hospital. This is the second donation given by the company.

ON the 15th inst., the corner stone of a new ward at the Rotherham Hospital was laid with full Masonic honours. The cost of the extension is estimated at £1000.

THE annual meeting of the supporters of the Ardwick and Ancoats Hospital and Dispensary was held on the 21st. inst, when a fairly satisfactory financial report was presented.

AT Ludlow on the 20th inst., Mr. John Adley, a former mayor of that place, was in his garden attending to his bees, when they swarmed upon him, stinging him so severely that he died before medical assistance arrived.

THE Liebig Monument Fund amounts to 25,000 dollars, and the monument will be erected in Ziessed, a small Hessian University town where Liebig first won fame as a lecturer on chemistry.

PROPOSED HYGIENIC INSTITUTE IN VIENNA.—It had been proposed to build a large Hygienic Institute in Vienna, but, unfortunately, the means are not forthcoming at present, so the project is necessarily in abeyance.

DR. MAX BRUBERGER.—The death is announced in Berlin of Staff Surgeon Dr. Max Bruberger, who has been for many years one of the editors of the German military medical journal.

A SUPERANNUATION allowance of £120 has been awarded to Mr. Beardshaw, the retiring medical officer for the No. 2 district of the Leeds Union.

HOSPITAL SUNDAY.—The Lord Mayor has received, at the request of the Prince of Wales, through Sir P. Cunliffe-Owen, a cheque for £100 for the Hospital Sunday Fund, being the amount received up to the present time in Dr. James Aveling's "Mechanical Begging Boxes" at the Colonial and Indian Exhibition.

GREAT NORTHERN CENTRAL HOSPITAL.—At the half-yearly meeting of the general council of this institution on the 15th inst., it was stated that a contract for building the new hospital in the Holloway-road, amounting to £40,300, had been accepted, and as the need of the new buildings was very pressing the work would be commenced at once. Not one-fourth of the sum required has as yet been subscribed.

ANNUAL INSPECTION OF THE VOLUNTEER MEDICAL STAFF CORPS.—On Saturday, July 17th, the principal medical officer of the Home District, Sir James Hanbury, K.C.B., held his annual inspection of this corps. He was accompanied by Surgeon H. R. O. Cross, Grenadier Guards. The members of the corps mustered to the number of 296. In their full dress kit they looked imposing. Since last year the physique of the men seems to have improved considerably. Sir James made a most minute inspection of the corps, and had each company paraded before him, and every officer had to come out in front of his company and drill the men. The following manœuvres were gone through:—Wheeling into line, open order for inspection, marching past in column, formation of a bearer company, rendering first aid in the field, waggon loading, &c. The inspecting officer finally congratulated the commandant, officers, and men on their smart appearance and on the way in which they had gone through the severe test to which he had submitted them.

PRESENTATIONS.—J. Oswald Lane, M.D. Cantab. &c., has been presented with a clock, pencil case, &c. by the pupils and nurses of the Northampton Infirmary on his resigning the post of house-surgeon to that institution, which he has held more than four years.——On the 12th inst. a number of members of the late Ambulance Class held in connexion with the 2nd Volunteer Battalion (the Queen's Own), Royal West Kent Regiment, conducted by Surgeon-Major Purvis, presented him with a walking-stick bearing the regimental crest and motto and a suitable inscription.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BINDLOSS, EDMUND FREDERICK, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer to the Deptford West District, vice C. H. Leftwich, resigned.

ERENNER, JAMES, M.B., C.M.Aber., has been appointed Medical Officer to the Parish of Resolis, Ross-shire.

BRITTON, THOMAS, M.D., M.R.C.S., L.S.A., S.Sc.Cert. Camb., has been appointed Honorary Consulting-Physician to the Halifax Infirmary, on his resignation as Honorary Physician and Honorary Medical Officer to the Harrogate Bath Hospital, vice Somerville, deceased.

BURTON, S. HERBERT, M.B.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Henstead Rural Sanitary District, Norfolk, vice Pitt, whose appointment has expired.

CROWTHER, GEORGE DODSON, L.R.C.P., L.R.C.S.Ed., L.S.A., has been appointed Honorary Medical Officer to the Halifax Infirmary.

HASON, A. M., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer of Health for the Lytham Urban Sanitary District, and for the Preston Port Sanitary District, vice Fisher, resigned.

GOUGH, J. HARLEY, M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Wolverhampton and South Staffordshire General Hospital, vice Batterham, resigned.

MACKELLAR, ALEX. O., M.D., M.Ch. Q.U.I., F.R.C.S., has been appointed Surgeon to St. Thomas's Hospital, vice Mason, deceased.

PARKER, G. ROGER, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Lancaster Rural Sanitary District, vice Harker, resigned.

RAKE, HERBERT V., M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Fordingbridge Rural Sanitary District.

SANTI, P. R. W., M.R.C.S., L.R.C.P., has been appointed Resident Assistant to the Wolverhampton and Staffordshire General Hospital.

STEPHENSON, SYDNEY H. A., M.B.Edin., has been appointed Clinical Assistant to the Royal Westminster Ophthalmic Hospital, King William-street, W.C.

THOMAS, W. J., M.B., C.M.Edin., has been appointed Senior House-Surgeon to the Halifax Infirmary, vice C. D. Crowther, appointed Honorary Medical Officer.

TRUMAN, C. E., M.A.Cantab., M.R.C.S., L.D.S., has been appointed Dental Surgeon to St. Thomas's Hospital, vice Ranger, resigned.

Births, Marriages, and Deaths.

BIRTHS.

COOKE.—On the 10th inst., at Warrior-square, St. Leonards-on-Sea, the wife of John Cooke, M.B Lond., of a daughter.

DUKE.—On the 14th inst., at 16, Pevensey-road, St. Leonards, the wife of Edgar Duke, M.R.C.S., of a daughter.

HORNE.—On the 14th inst., at Victoria-terrace, Stockton-on-Tees, the wife of Thomas Horne, L.R.C.P.Ed., L.R.C.S.Ed., L.M., of a son.

NORTON.—On the 15th inst., at Upper Gloucester-place, the wife of G. Everitt Norton, M.R.C.S., of a daughter.

PATERSON.—On the 19th inst., at 13, Cheyne-gardens, Chelsea, the wife of A. Gordon Paterson, M.B., C.M., of a son.

THOMPSON.—On the 15th inst., at Cavendish-square, the wife of E. Symes Thompson, M.D., F.R.C.P., of a daughter.

MARRIAGE.

DAVIS—CANDLER.—On the 14th inst., at the Wesleyan Church, Brixton-hill, Charles Daniel Davis, M.R.C.S., L.D.S.Eng., to Nellie, daughter of George Candler, of Newlands, Brixton.

DEATHS.

GWYNNE.—On the 16th inst., at Holloway, Ruby Imogen Ethelwyn, only child of John Hickling Gwynne, aged 10 months.

JAMESON.—On the 6th inst., at Lympstone House, Lympstone, Devonshire, Thomas Ross Jameson, M.D., Inspector General of Hospitals.

NASH.—On the 15th inst., at Royston, Cambs., Frederic Nash, M.R.C.S., of Todmorden, in his 50th year.

RANSFORD.—On the 11th inst., at St. Cross Hospital, Winchester, Chas. Ransford, M.D.Edin., F.R.C.P., L.R.C.S., aged 78.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE DICTIONARY OF PRACTICAL SURGERY.

Mr. Paul Swain writes to enter a demurrer against our criticism of his assertion that "the application of nitrate of silver to the prostatic urethra is of service in the treatment of that most pernicious habit." Mr. Swain desires to point out that the application in question was suggested as a cure for one of the frequent results of masturbation—viz., nocturnal emissions, and that if he is wrong he has erred in good company, as Messrs. Erichsen, Bryant, and Humphry have, in their writings, advocated the same procedure.

Enquirer.—The Education Department has decided that whenever a certificate is required in explanation of the absence of a child from school, the cost of the certificate is to be defrayed by the School Board.

PERIODICAL BILIOUS ATTACKS.

To the Editor of THE LANCET.

SIR,—I have a lady patient, aged thirty, who has for some years been suffering from severe bilious attacks, each attack coming on regularly at intervals of three or four weeks, and with the same premonitory symptoms—viz., feeling of lassitude, nausea, severe headache, dizziness, muscæ volitantes, followed by copious vomiting of bilious matter. A day or two afterwards she seems quite herself again. She was treated with mineral acids, mercury, podophyllin, &c., but with negative results. Can this be due to stricture of the duct, the result of inflammatory thickening of the mucous membrane? I should esteem it a great kindness if any of your many readers could suggest a remedy whereby the patient might be relieved of these attacks.

I am, Sir, yours faithfully,

Ipswich, July 21st, 1886. L.R.C.P.

A NEW SOLVENT OF URINARY CALCULI.

AT a recent meeting of the French Therapeutical Society a specimen of pichi, or piché, was shown by M. Limousin. In its native country (Chili) it was believed to disintegrate urinary calculi. M. Limousin expressed the belief that pichè acted especially on the mucin, which held together the different elements of calculi and dissolved it, and lessened vesical catarrh, a belief which, in consequence of the resin it contained, was shared and confirmed by M. Dujardin-Beaumetz. A fluid extract has been prepared, of which four dessertspoonfuls represent thirty grammes of the plant, the dose generally administered in twenty-four hours.

Mr. R. Hingston Fox.—Very soon.

Lectures
ON
DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

BY HENRY POWER, F.R.C.S.

LECTURE I.—PART I.

DISEASES OF THE LACRYMAL GLAND.

GENTLEMEN,—The diseases of the lacrymal organs have attracted the attention of surgeons and physicians from the most remote periods, for it was impossible that inflammations and tumours of these parts, with their attendant symptoms of pain and redness, closure of the lids, temporary loss of vision and oftentimes severe constitutional symptoms, could be overlooked; and we accordingly find that the oldest practitioners with whose writings we are acquainted—Galen, Celsus—nay, even Hippocrates himself—described the symptoms, devised means of relief for the acute kind, and suggested various proceedings to prevent their recurrence.

The lacrymal apparatus is of a very complicated nature; the causes leading to disease in it are very diverse: the conditions presented vary greatly in different cases, and require for their treatment a corresponding knowledge and intelligence on the part of the surgeon. It is not surprising, then, that the treatment adopted, from limited experience in one class of cases by one surgeon, should be found wholly inadequate and inefficient by others in a different class; and hence has arisen a wealth of remedial means, and such an armamentarium of instruments as is scarcely to be equalled in any other department of surgery—a sure sign of uncertainty in their application and disappointment in their effects.

An additional reason for the unsatisfactory nature of our treatment of lacrymal disease is to be found in the circumstance that we possess very little information in regard to the morbid conditions which accompany or cause the diseases that are so familiar to us. I think I am correct in saying that neither in this museum nor in any other belonging to the great schools of the metropolis, with the exception of St. Bartholomew's, is there a single preparation showing the normal or diseased condition of the lacrymal apparatus. Lacrymal disease does not prove fatal, and when it has been known to exist, the condition of the lacrymal gland, sac, and duct has not been investigated, because such an examination would involve very considerable disfigurement of the face. Nothing, in fact, can show more clearly the great importance, in the scientific development of medicine and surgery, of a thorough knowledge of pathology. If we possessed such knowledge in the case of lacrymal disease, our treatment, which is now purely empirical, would at least become rational, and the various plans of treatment which have been found occasionally to prove successful, and very frequently to fail, would be applied in those cases only for which they were especially adapted.

A few facts in regard to the statistics of lacrymal disease may be mentioned. Taking three years, and using the numerous tables of various ophthalmic institutions and practitioners in Michel's *Jahresbericht*, it appears that the proportion of lacrymal diseases of all forms to other diseases of the eye in a total of 500,000 is about 3 per cent. This may be taken as well assured, though special observers vary in their statements from 2 per cent.[1] to 6 per cent.[2] The records of the books of St. Bartholomew's Hospital show that during the ten years from Jan. 1st, 1874, to Dec. 31st, 1883, the total number of in-patients was—males 1685, females 1430. The number of cases of lacrymal disease amongst the males was 27, or 1·6 per cent. The number of cases of lacrymal disease amongst the females was 61, or 4·26 per cent. Taking both sexes together, the proportion is 2·8 per cent. The records of the out-patient book show that during the same period there were in attendance 2337 males and 1934 females. Disease of the lacrymal apparatus was noted in 71 males and in 119 females, or 3·16 per cent. of the males and 6 per cent. of the females, or together 4·58; but some of these were probably discharged in-patients who were directed, on leaving the hospital, to return in order that treatment might be continued. The diseases of the lacrymal gland appeared to be more prevalent in some years than in others. Thus, whilst there were 8 cases in 1874, 12 in 1875, 11 in 1876, and 11 in 1877, in 1878 the number rose to 38, and in 1879 there were 32 cases; in 1880 the number fell again to 11, in 1881 it was 17, in 1882 it rose to 33, and in 1883 it was 17.

It is acknowledged by all who have compared the numbers that women are much more subject to lacrymal disease than men, the proportion being about two or even three to one. Thus, Nieden found in his practice 62·1 per cent. of females and 37·9 of males; v. Hasner, 74·5 per cent. of females and 25·5 of males; Schirmer, 67·0 per cent. of females and 33·0 of males. The cause of this disposition on the part of women is not easy to explain. Men are certainly more exposed to variations of weather; but their activity is greater, and we may refer the difference with some probability to the sedentary occupations of women, to their greater proclivity to tears, and perhaps to the smaller calibre of all the ducts.

Nieden has advanced evidence to show that there is a hereditary tendency to lacrymal disease in all its forms—epiphora, stricture, and dacryocysto-blennorrhœa. In 9 per cent. of all lacrymal affections parents and children were affected, and the proportion in which the hereditary transmission occurred from mother to child was 63·3 per cent., whilst from father to child it was only 36·7 per cent. There was thus shown to be a special predisposition in children whose mothers had been affected. All authors agree that the lacrymal organs of the left side are more liable than those of the right. The following table shows the proportion in percentages:

	v. Hasner.		Schirmer.		Mooren.	Nieden.	
Both eyes	11·8	...	29·3	...	13·7	58·0	
Right eye	32·2	82·2	25·6	70·7	86·3	26·2	42·0
Left eye	56·0		45·1			15·8	

The nomenclature of the different affections of the lacrymal apparatus varies so much that it is difficult to draw any conclusions as to their relative frequency. For example, in the very complete statistics issued by the Presbyterian Eye, Ear, and Throat Charity in the States, there were 148 cases of abscess of the sac in 939 cases of lacrymal disease occurring amongst 22,335 general patients. Mooren, on the other hand, amongst 32,425 ophthalmic patients, only met with one case of dacryo-cystitis, which, if not a typographical error, is remarkable.

Having made these preliminary observations, I think that this lecture may be profitably devoted to the diseases of the lacrymal gland. I do not propose to enter into minute detail in regard to its structure, because when I had the honour of being the Arris and Gale Lecturer in this place I gave as fully as I was able the results of modern histological research. Nevertheless, it may be worth while to recapitulate the chief points of interest in regard to the anatomy and physiology of the gland and its secretion. In the first place, then, the lacrymal gland is divisible into two parts: a larger solid bean-shaped body, occupying the hollow in the outer part of the orbital plate of the frontal bone; and a smaller, thinner, or flattened portion, separated from the former by a fibrous septum, and lying in front of and beneath it. The former is the ganglion innominata of Galen, the latter the accessory gland of Rosenmüller, and they are sometimes named the orbital and palpebral portions of the gland. The orbital plate of bone is curiously cancellous in some skulls at the part where it has been in immediate relation with the gland, as is well shown in this negro's skull. [No. 1225, Negro, Hunterian Museum.]

The histological characters of the orbital portion of the lacrymal gland are those of an albuminous gland. In the fresh state the cells are so crowded with granules that their limits are not easily defined, though they may be rendered distinct by the addition of dilute acetic or chromic acid.

[1] Hasner: Beiträge zur Anat. und Phys., des Thränenableitungs apparat. Prague, 1850, p. 66. [2] Wecker, 1st edition.

They possess an oval nucleus. The cell protoplasm is finely fibrillated. When stimulated (Reichel[3]) the cells, like those of the albuminous glands generally, become smaller and more granular. Heidenhain[4] remarks that the excretory ducts of the lacrymal gland differ from those of other albuminous glands in the absence of the usual rod-like character of the cells. In many parts there are blind tubes lined with columnar epithelium. The glands are fairly supplied with bloodvessels, the chief artery being a special branch of the ophthalmic. The nerves supplying the gland are derived from the fifth and sympathetic, as well as perhaps from the subcutaneous malæ; and Boll describes both medullated and plain nerve fibres running to the alveoli, whilst numerous branched cells are found between the alveoli, the communication of the processes of which form a kind of plexus. Under ordinary circumstances the orbital portion of the glands acts only very slightly or not at all. On the other hand, there is pathological evidence to show that the palpebral portion always secretes and aids in maintaining the brightness and polish of the cornea. The secretion of tears can be called forth by exposure of the nerves in the orbit and stimulation by electricity or other means. Usually, however, it results from reflex stimulation, either through the sensory branches of the fifth distributed to the conjunctiva or nose, or through the optic nerve, on exposure of the eye to a bright light, by strong irritation of almost any sensory nerve, by mental emotion, and by any condition causing flushing of blood to the head. Stimulation of the sympathetic causes the secretion to become cloudy. Section of the fifth has been observed to be followed by paralytic secretion.

The quantity of tears secreted is believed by Magaard[5] to be at the rate of one drop per twenty minutes. They are clear, watery, alkaline, and of saline taste. The composition of the tears probably varies in different people, but the fluid usually contains only 1 per cent. of solids, the chief salt being sodium chloride.

Luxation. That, well protected as the lacrymal gland is, it may be luxated either by external violence or by disease developing in the deeper parts of the orbit, is demonstrated in various cases that have been reported. One of these is given by Dr. Rampoldi[6], in which a blow with a stick in the temporo-parietal region was followed in the course of a month by the formation of a retro-bulbar abscess. An opening was made at the upper and inner part of the orbit and the pus evacuated; a drainage-tube was inserted and antiseptic injections employed. The exophthalmos subsided, and there was no impairment of vision. Osteo-periostitis with a fistulous passage formed, and gradually ectropion took place; the lid became quite everted, and so much retraction occurred that the gland was gradually luxated from its position and drawn down till it appeared beneath the conjunctiva. Finding that he could not replace it, M. Rampoldi destroyed it by the plan suggested by Borelli to remove staphyloma. A case has been recorded by Snell,[7] and another has been met with by v. Graefe,[8] in which prolapse of the gland occurred as the result of an injury. It is to be noted that in such cases the ablation of the gland is not to be taken as a matter of course, for v. Graefe replaced it in its natural position, applied a suture or two to the eyelid, and cured the patient.

Dacryo-adenalgia.—Persistent pain of the lacrymal gland, long ago diagnosed and described by Schmidt under the term "dacryo-adenalgia, is characterised by severe tension and lancinating pain in the region of the gland. Intolerance of light is experienced, but there is or may be no suffusion of the conjunctiva. The chief symptom appears to be great increase in the quantity of secretion discharged, which in one instance reported by A. Schmidt amounted in twenty-four hours to no less than 2 lb. 7½ oz. In such cases the lids are apt to become sore. A scrofulous inflammation of the globe of the eye extending to the gland may be the primary cause of this lesion. The affection increases gradually in intensity, and it has no tendency to run into suppuration. It occurs most frequently in children, in women, especially in the puerperal state, and may be the consequence of undeveloped gout. The conditions that cause or, at least, intensify it are exposure to bright light, disturbance of the cutaneous or other secretory organ, mental excitement, and great variations of temperature. The prognosis is, on the whole, favourable; but the affection is liable to become chronic, and relapses are apt to occur.

The treatment consists in the application of heat, care being taken not to arrest the secretion too suddenly lest violent inflammation supervene. Hence, warm ethereal or spirituous applications are best, especially poultices of ethereal plants, infrication of mercury and of camphor, with or without opium. The general treatment is of still greater importance, and the remedies applied must be adapted to restore the bodily health of the patient. Locally, a solution of five grains of watery extract of opium to an ounce of water, with spirit of chamomile, compresses of lukewarm water, renewed every hour, and poultices of alum or zinc sulphate, are the applications recommended by the authors I have mentioned.

I have seen one case of this disease in a stout woman aged sixty. The pain was accompanied by violent itching, which caused her to rub the eyebrow so much that she had rubbed off all the hairs. She attended the hospital at intervals for several years and a great variety of remedies were tried for her, both local and general, but without effect. No cause could be ascertained for the affection.

Dacryo-adenitis.—Inflammation of the lacrymal gland is undoubtedly a rare disease, both in its acute and chronic form. Arlt[9] states that he has never seen a case of it. Desmarres[10] observes that in a large practice extending over many years no example had fallen under his notice. Deval,[11] perhaps with more accuracy, states that he has never been able to diagnose a case. Hirschberg[12] says that he only saw one case of suppurative inflammation of the gland in 22,000 cases. Galezowski,[13] during the four years he was chef de clinique to Desmarres, saw no example of it. Lawrence[14] observes: "I do not remember having seen either of these affections" (acute or chronic inflammation), and he thinks he must have either overlooked diseases of this organ which have been noticed by others or have mistaken them for other affections. Nevertheless, in support of his own observation, he goes on to say that in twelve of the annual reports of diseases treated at the London Ophthalmic Infirmary, embracing a total of 40,000 cases, the lacrymal gland is not even mentioned in the list of diseases. There is only one case of abscess of the lacrymal gland referred to in the indices of the Royal London Ophthalmic Hospital Reports. Beer, whose practice was very large, only saw it a few times in the course of twenty-seven years. Velpeau, commenting on the exceptional rarity of inflammation of the lacrymal gland, compares it with the pancreas in this respect. He had seen three cases of the disease.

It is not difficult to assign reasons why inflammation of this gland should be of exceptional occurrence, for it occupies a position that is remarkably protected both from injury and from cold. Then, again, the product of its secretion is of so limpid and watery a character that concretions from inspissation or deposition are extremely rare, whilst it is discharged by ducts which, though very fine, are yet numerous, and perhaps communicate, so that there is little risk of the secretion being retained. Indeed, an arrest of the discharge of tears, either by constriction or occlusion of the ducts, is very rarely seen even by those who have large opportunities of treating ophthalmic diseases, and I only know of one instance where congenital absence of tears has been observed. This case was a child exhibited by Mr. Stanford Morton to the Ophthalmological Society on Jan. 10th, 1884. No tears had ever been seen to flow from the right eye. The difficulty that is experienced in diagnosing inflammatory affections of this gland from inflammation of the lids and of the connective tissue of the orbit, hinted at by Mr. Lawrence, is occasioned by the depth at which it is situated below the surface, and by the swelling of the lids which accompanies any inflammation at the upper and outer part of the orbit, which renders it difficult to determine whether the gland is really swollen or not. Nevertheless, however rare in the practice of some surgeons, it has occurred with much greater frequency in that of others. Schmidt, for example, who wrote a treatise on the diseases of the lacry-

mal organs, met with and described many cases; Todd had the same fortune; Travers[15] says that the gland often suppurates in children. Lawrence, in alluding to these cases, sarcastically observes that he has met with some recorded cases in which inflammation and suppuration of the lacrymal gland are *said* to have occurred. "The mischief began in these instances with a blow. I believe them to have been merely abscesses of the lid; at least, I see no circumstances to prove that the lacrymal gland was involved in the affection."

Galezowski, in the memoirs just referred to, reports nine cases that have occurred under his observation, and he notices that they presented an epidemic character; for whilst he only saw one case in each of the years 1869, 1875, and 1880, there were no less than six in 1875, and in this year mumps was prevalent. It is probable that this affords some clue to the varied experience of different surgeons, and some support is given to it by the history of a case reported in the Transactions of the American Society of Ophthalmology two years ago by Pooley,[16] which is suggestive in this direction. The interesting and unusual feature in this case was the occurrence of an acute inflammation of the gland during the course of an acute diphtheritic inflammation of the other eye, raising the question in my mind whether it might not have been caused by septic absorption. In the discussion which followed the reading of Dr. Pooley's paper, however, Dr. Knapp observed that the cases he had seen had no infectious origin, and in the majority of cases there was no conjunctival complication.

In acute inflammation of the lacrymal gland, the patient, after suffering from chills and general malaise for a day or two, experiences sharp lancinating pains in the region of the gland, extending over the side of the head and towards the parotid gland, which is usually swollen and tender. The conjunctiva is either dry or moister than natural, and the swelling of the gland causes the globe of the eye to be displaced downwards and inwards, so that squinting and diplopia occur. Any rolling movement of it is painful, and it is sensitive and tense. There is usually considerable redness and swelling of the upper lid, especially near the outer angle, and this occasions a mechanical ptosis, the patient being unable to raise the lid. It is tender to the touch. In the earlier period of the disease the margin of the gland can be recognised as a hard resistant border, with a groove between it and the margin of the orbit, and at this period, on raising the upper lid, the gland may be seen to project into the conjunctival sinus. At a later period the swelling of the lid is too great to allow the gland to be either felt or seen. The conjunctiva is generally red, inflamed, and chemosed, especially near the outer canthus. If the disease develop rapidly, the symptoms described by some authors probably occur such, for example, as cerebral excitement, sleeplessness and delirium, which have been attributed in part to the pain, and in part to the implication of the dura mater. Himly,[17] who speaks as though the affection were of common occurrence, remarks that the symptoms of the acute stage are followed by a period when the acute stabbing pain ceases, whilst the tension still remains extraordinarily great and a feeling of pressure and of cold is experienced. The pressure of the swollen gland interferes with the function of the optic nerve, and photopsiæ or luminous phenomena and impairment of vision have been noticed, both probably arising from mechanical pressure upon the optic nerve. After a few days suppuration takes place, and gives rise to a feeling of fluctuation beneath the skin and orbicularis, through which it ultimately bursts near the outer angle or into the conjunctival sac.

The causes to which it has been attributed are rheumatism, sudden exposure to cold, especially in gouty subjects—as, for example, immersion in cold water whilst heated and perspiring; and Schmidt, Travers, and Galezowski consider that children of a scrofulous habit of body between the ages of seven and twenty are especially liable to it. In Galezowski's seven cases, however, the ages were sixteen, twenty-six, twenty-six, twenty-seven, forty-eight, and fifty-six—ages which do not bear out the above statement. Of these cases four were males and three females. I have seen three cases at least, and these were all in women; one was twenty-four, the second thirty-four, and the third forty. Acute inflammation of the gland has been observed to recur. Fulton[18] gives a case of acute primary inflammation of the lacrymal gland occurring twice in the same individual. The patient was a woman aged twenty. No cause could be assigned for the affection. An interval of three years occurred between the attacks. Both attacks subsided under general and local antiphlogistic treatment: leeches, hot compresses, and iodide of potassium. In some fortunate cases the inflammation terminates in resolution, and the patient suffers no further inconvenience, the swelling gradually diminishing, and the eye, if affected, resuming its function. In other instances the acute inflammation subsides, but is succeeded by chronic enlargement and tenderness. In still other cases suppuration takes place in the course of a week, and recovery follows, though usually with some secondary trouble, such as the formation of a fistula or a puckered cicatrix and retraction of the upper lid, and not unfrequently considerable impairment of vision.

As regards treatment, the abortive plan may be tried in the early stages of the inflammation, with the view of preventing the occurrence of suppuration. An emetic may be administered, and after it has acted a mixture containing quinine and iodide of potassium should be prescribed. Locally, the best means to employ are six or eight leeches to the eyelid, and lotions containing belladonna and acetate of lead, or the upper lid may be brushed over two or three times with iodine tincture. When the pain is very severe opium should be given. When it is clear that pus has formed, the earlier it is opened the better for the patient. As already stated, a delicate sense of touch is required to recognise the presence of pus when deeply seated and covered by such a tissue as the œdematous eyelid, and little benefit accrues from plunging a knife into the gland whilst the abscess is still immature. Travers[19] states that the abscess, when it has maturated, may be conveniently discharged beneath the lid with a narrow curved bistoury. Himly,[20] on the other hand, recommends that the abscess be opened through the skin with a lancet, the flat surface of which is kept parallel with the fibres of the orbicularis; and he maintains that owing to the swelling of the lid it is seldom possible to open it through the conjunctival sinus, though he was on one occasion able to accomplish it. A tent soaked in boracic acid may be left in the wound, even when it has been opened under very strict antiseptic methods, in order that the cavity of the abscess may granulate from the bottom. In many instances the inflammation has been so violent that the margin of the orbit or the orbital plate of the frontal bone is necrosed, and the abscess, instead of healing completely, ends in the formation of a fistulous passage, into which a probe may often be passed for a considerable depth, and then strikes on rough and exposed bone. Under these circumstances a free incision should be made, and the diseased bone brought into view, and if possible gouged or rasped away. When, however, the orbital plate of the frontal bone is necrosed, it must be left alone till it has completely separated. It must be remembered that the plate is very thin, that the substance of the brain cortex is in very close proximity, and that laceration of the surface, or its penetration by splinters of bone, or even the mere entrance of pus into the vessels and into the cavity of the cranium, might be attended with fatal results. In some cases the fistulous opening appears to communicate with one of the ducts of the gland, and in that case a minute opening appears upon the skin or upon the conjunctival surface, from and through which a clear transparent fluid constantly distils in drops. This affection is termed "dacryops," or true lacrymal fistula.

Non-suppurative acute dacryo-adenitis, which has been termed "mumps of the lacrymal glands," is also rare. Hirschberg reports a case occurring in a girl aged fifteen. There were bilateral swelling and injection of the upper lid, without chemosis or lacrymation. The swollen glands could be distinguished by palpation. Poultices and iodide of potassium were prescribed. Moderate chemosis subsequently occurred, and the right globe was displaced, causing diplopia. This state was persistent. The chronic form, according to Hirschfeld,[21] is not so exceedingly rare, but is generally secondary. It originates in scrofulous patients

with protracted keratitis and profuse lacrymation. A reddish, tongue-shaped swelling, with granular surface, becomes visible between the upper lid and the eyeball towards the outer canthus when the patient rotates the eye downwards whilst the lid is raised.

TONSILLITIS, AND ITS RELATION TO SCARLATINA AND DIPHTHERIA.[1]

BY R. HINGSTON FOX, M.D., M.R.C.P.

INFLAMMATIONS of the tonsils present manifold varieties and gradations. It is convenient to include in the general term "tonsillitis" some forms of inflamed throat in which the implication of the tonsil is a less striking feature. The tonsils do not stand alone, but the mucous membrane in their vicinity is studded with nodules of similar structure—i.e., of lymphatic tissue; these are most abundant on the back of the tongue at its root, but exist also on the sides of the faucial aperture. The presence of these lymphatic organs is an especial characteristic of the fauces, and inflammations of the fauces, involving these structures generally, may well be included in the forms of tonsillitis. Catarrh of the fauces, however, such as is associated with nasal and pharyngeal catarrh, will not be considered here; it involves the tonsil little, if at all, and occurs in a different class of subjects from that affected by ordinary tonsillitis. Passing over the specific varieties, due to syphilis, tubercle, variola, &c., we meet commonly with certain clinical types of tonsillitis. By *true quinsy* I mean the recurrent "inflammatory sore-throat" (Trousseau), which results in abscess in or (more often) about *one* tonsil. The sudden onset, acute pyrexia, and rapid inflammatory œdema are distinctive features. We come next to the common tonsillitis, long since clearly described by Dr. Anstie,[2] who distinguished it from the suppurative form. The term "follicular" is often applied to this affection, being derived from the fact that the crypts on the surface of the tonsils, formerly called follicles, are often plugged with exudation (hence "spotted throat"); it is a bad designation, since the word "follicle" is now more often applied to the nodules of lymphoid tissue of which the gland consists. The name "septic tonsillitis" is provisionally adopted here.

A family of four children (age from four to eight years) began to ail three or four days after their return from the seaside in September, 1884. The eldest girl was affected with headache, sore-throat, coated tongue, and loss of appetite. The other three children followed. Each was slightly feverish, the highest morning temperature (in the mouth) being 100·1°, 100°, 99°, and 100·8°. The fauces were red, both tonsils were swollen, and in one case they presented little pocky eminences. Within a fortnight all were well. Some of these children have at various times suffered from sore-throats, true diphtheria, severe mumps, and rheumatism, as well as chronic enlargement of the tonsils. In searching for the cause of the tonsillitis, it transpired that, on their arrival at home, the children had drunk greedily from a covered in-door cistern in which the water had stood stagnant and tepid for several weeks.

These cases exemplify the leading features of septic tonsillitis in a mild form; its attacking a group of persons in one household, often children; the brief pyrexia; both tonsils are attacked at once, being swollen and reddened, and they may present small yellowish or greyish white patches. There is not the acute infiltration of the surrounding tissues seen in true quinsy. The cause seemed in these cases to be derived from impure drinking-water. Dr. Anstie attributed the affection to defective drainage or ventilation. As a rule there is no evidence of communication from one person to another.

This disease has now and then prevailed in extensive outbreaks—either in a certain district, or in a school or other large institution. Instances of the first are reported by Dr. F. P. Atkinson and others,[3] and by several French writers (Morell Mackenzie); of the second, by Mr. G. A. Cardew of Cheltenham,[4] and by Dr. Haig-Brown of Godalming in a paper lately read before the Association of Medical Officers of Schools. Is there any connexion between septic tonsillitis and true quinsy? Most English writers still make no distinction between them. Yet in typical cases they appear wholly distinct. Suppuration perhaps occurs in rare cases of the former affection, but this would not prove any connexion with true quinsy.

Tonsillitis, often of a severe type, is a prominent symptom in both scarlatina and diphtheria. This will be again referred to.

We pass on to cases of a more mixed and doubtful character. In the Proceedings of the Medical Society of London[5] outbreaks of "infectious sore-throat" are described by Drs. Farquharson, Routh, and Crisp. Dr. Routh's 46 cases occurred in a public institution in which the drinking-water was impure. Three types were distinguished—simple cynanche, sore-throat with diphtheritic patches, and scarlatina. Dr. Crisp's outbreak was located in Chelsea along the river-side, and was attributed to the opening of some large drains. There were 42 cases of "mild scarlatina," mainly in children, and 56 cases of "epidemic sore-throat" with large inflamed tonsils, mainly in adults who had had scarlatina already. Outbreaks of this mixed character have been described in several of Mr. W. H. Power's reports,[6] and by Mr. Hartnoll[7] of Exeter; others have been recorded by Dr. Bond[8] of Gloucester, Dr. Mantle[9] of Chester-le-Street, and Dr. J. Craig[10] of Llandudno. The last three accord with the description of "pseudo-diphtheritis" given by Dr. H. Ashby of Manchester in the *Practitioner* (vol. xxxi., p. 414).

These records show that it is not uncommon, in the presence of faults in the air or water supply, for temporary outbreaks of mixed forms of tonsillitis to occur, sometimes infectious in their character. Cases which would commonly be described as scarlatina and as diphtheria, with others of mere tonsillitis, are found together, with cases of a mixed type, wellnigh impossible to assign to either of the former classes, and all apparently depending upon a common cause. Or the latter type may alone be present (pseudo-diphtheritis). Such outbreaks seem to hold an intermediate position between tonsillitis and the specific fevers. This leads me to the following proposition: that scarlatina and diphtheria may be regarded as essentially forms of tonsillitis which have acquired infective characters; that is, they differ from other forms of tonsillitis in having the power of *infecting the system* generally, and producing the phenomena of a specific disease. In speaking of these diseases as forms of tonsillitis, I would not do so in any narrow sense. They belong probably to that large class of diseases whose poisons reach the blood by way of the lymphatic system, their distinguishing character being that they are prone to enter that system through the tonsil, setting up tonsillitis. In ordinary tonsillitis the poison scarcely gets further than the tonsil. The term "poison" is here used as a convenient expression for the organic *materies morbi*, capable of multiplication, and including (it is probable) both a bacterium and the products of its growth.

I digress here to say a few words on the functions of the tonsils in health. These organs consist of a mass of closed sacs or nodules, identical in structure with those of the solitary and Peyer's glands, and indeed of the ordinary lymphatic glands of the body. Some small mucous glands open into the crypts on the surface (Landois), but these are quite insignificant. The old view that the tonsils are secreting organs is untenable, since their structure is that of absorbent glands in general, aggregations of leucocytes enclosed in retiform tissue. Their functions also must be of the absorbent kind. In the July number of the *Journal of Anatomy and Physiology* I show some grounds for believing that this absorbent function is connected with the saliva; that from the constant slow stream of salivary fluid which is passing over their surface during the intervals between meals, the tonsils, being themselves nurseries of young leucocytes, absorb certain elements to minister to the growth of the white cells. This theory is not in any way essential to the present argument, but if true it would afford an interesting parallel, showing how closely pathological processes follow on the lines of physiology. Thus, in

[9] See Dr. Mantle's paper in British Medical Journal, 1885, vol. ii., p. 960. Dr. Mantle informs me that he sees many such cases, unequivocally infectious, occurring "in a crowded colliery district ..... houses too crowded and badly ventilated, and drainage very defective."

[10] British Medical Journal, 1886, vol. i., p. 110.

health, food matter, perhaps a ferment, would be absorbed from the saliva and stimulate the tonsil to healthy activity. In disease, a poison, perhaps also a ferment, is absorbed from the saliva[11] and over-stimulates the tonsil; there is over-activity, multiplication of ill-formed cells, and other phenomena of inflammation.

To resume, the poison of septic tonsillitis gives rise to the clinical signs of a process of this kind, and little more. The products of its growth do, indeed, enter the system, and cause some brief constitutional disturbance; but the living poison itself has little power of overcoming the resistance of the tissues. The system is not infected by it; it soon dies or loses its toxic properties, being incapable of reproducing itself in the human body to any great extent, if at all. Other poisons of the same class, but better adapted for living in the human organism, thrive therein, infecting the system generally, and producing symptoms of graver character and longer duration—in fact, running through the course of a specific fever (scarlatina or diphtheria). Such a poison is able to go on reproducing itself in the human tissues for a considerable period, and without losing its poisonous properties, so that by the time it is (to adopt Dr. Fagge's expression) destroyed by the pyrexia which it has set up it has caused the series of lesions belonging to the specific fever. It has also by this time become enormously multiplied, and particles of the tissues containing the poison being shed and communicated to other human beings, set on foot in them like processes, being, in fact, *contagia*. Now, in the power which the poison possesses of so far overcoming the resistance of the tissues of the human body as to reproduce itself largely therein without marked deterioration, so that offspring remotely removed from the original stock still produce the same effects in the tissues of a fresh human subject,—in this power may we not recognise the characteristic of a *species* of disease? Some affections—e.g., various forms of infectious sore-throat—possess this power in a limited degree, and chiefly when associated with septic conditions (as the presence of putrefying matter in air or water, &c.); but scarlatina has apparently an indefinite power of reproduction, and largely independent of septic conditions. In accordance with the doctrines of evolution, we may suppose that the specific poison has been gradually developed from the group of non-specific poisons of tonsillitis, which present a varying capacity of infecting the system.

The above scheme contains much that is hypothetical, but it furnishes an explanation of the facts already stated, especially of the occurrence of "intermediate forms." Some further facts will now be added in support of the theory. It is a frequent observation, made by Trousseau and by many others since, that common tonsillitis is very prevalent when either scarlatina or diphtheria is epidemic. Again, all these diseases are often either dependent for their spread on septic conditions, or are more active under such conditions. Some believe that scarlatina occasionally arises *de novo* under such circumstances,[12] whilst many consider that diphtheria so arises.[13] "A striking feature of scarlatina is the great variability of its symptoms and of its course" (Fagge). Tonsillitis is, I submit, the most constant of its symptoms. It is notorious that in mild, scarcely recognised cases of scarlatina sore-throat is the only symptom observed. Yet such cases often communicate the disease.[14] In other rare cases it is stated that a rash has been present, and no affection of the throat. Space will not admit of reference to the literature of this subject; I will only say that there is fair ground for question whether a tonsillitis, too slight to cause any complaint, did not exist in all such cases. In some cases of scarlatina, again, we see the tonsils covered with a thick membranous investment. Thomas and others say that true diphtheria is then concurrent. Niemeyer, Senator, and I think most English authorities, hold, on the other hand, that diphtheritic pharyngitis may be the result of the scarlatinal poison alone. Whichever view be taken, there appears to be a close connexion between these two diseases.

Diphtheria has been classed as in an intermediate position between specific zymotic fevers and common local inflammatory diseases (Parsons), and some have even assigned it to the latter category. At any rate, it has not, as a specific fever, acquired the stability of scarlatina, measles, &c.[15] Oertels (in Ziemssen's Cyclopædia) and Loeffler have ably maintained that the process in diphtheria is at first entirely local, the constitutional effects being due to a poison developed at the seat of attack—i.e., at the fauces in ordinary diphtheria. The primary local lesion also presents great variety. Senator[16] describes four chief types, ranging from simple catarrh to fibrinous exudation. Yet the peculiar paralytic sequelæ may follow in cases where the throat lesion was so slight as to be unrecognised.[17] Some have maintained that ordinary tonsillitis is in rare instances followed by these paralyses.[18] Such cases surely belong to diphtheria; nevertheless, the statement illustrates our present point—the closeness with which this disease approaches to ordinary tonsillitis, so that there is hardly a line of demarcation between them.

In "surgical scarlatina," the disease is said to be contracted by inoculation of the highly absorbent surface of recent wounds. Such a surface may afford facilities for the entrance of the poison into the lymphatic system; this would not controvert the more usual entry at the tonsils. (The notion that the infection may be received by the unbroken skin is now generally abandoned.) Diphtheria of other mucous surfaces and of wounds presents us, perhaps, with a parallel condition to that last mentioned. Whether in such cases the fauces are afterwards affected is a question not yet fully settled.

This necessarily brief treatment of a large subject may seem inadequate. The theory advanced is an honest attempt to explain existing facts.

ABDOMINAL SECTION FOR DISPLACED HERNIA.

By E. WARD, M.A., M.B., B.C. CANTAB.,
SENIOR ASSISTANT-SURGEON TO THE LEEDS GENERAL INFIRMARY.

SOME years ago I assisted in the performance of an operation upon a young man who was suffering from intestinal obstruction. There was a history of congenital hernia, which had always been reducible. He had himself reduced it two days before, and had vomited almost continually ever since. The scrotal tissues were redundant, thickened, and lax; and the spermatic cord was obscured as by a hernial sac, which could not be separated from the testis, the latter being drawn up towards the external abdominal ring. There was a little fulness above the internal abdominal ring, with tenderness on pressure. Invagination of the scrotum through the inguinal canal showed that it was capacious, and that both the rings were much enlarged, but gave no further help in the diagnosis. It was decided to explore the inguinal region. The sac of a congenital hernia was opened, but, in spite of a free inguinal incision, the operator was unable to reach anything which could throw any further light upon the case; and it was with extreme difficulty that I, with considerably greater length of finger, could reach and bring down a knuckle of strangled bowel, and the patient was in some danger of remaining unrelieved. He made a good recovery.

The recorded cases of displaced hernia which have been relieved by operation are still comparatively few in number; and this fact alone would suggest the publication of the following case, even if it possessed no features of special interest; but I think that the method of operation, upon which I propose to offer a few remarks, is worth consideration, apart from the mere transference of the wound from the groin to the middle line of the abdomen. This, however, in itself is a gain; for although wounds of the peritoneum are not regarded with quite the same awe as formerly, we strive as far as possible, for reasons antiseptic, to keep them, in common with all wounds, away from the natural orifices of the body, and in situations where they can be easily, efficiently, and securely dressed. The notes of the case have been selected from the report of Mr. E. G. F. Morris, house-surgeon, and have been kindly arranged by Mr. Mayo, the resident surgical officer.

"James B— —, aged fifty-nine, was admitted at noon on

July 5th, 1885, suffering from symptoms of intestinal obstruction. He was a healthy-looking out-door labourer of fine physique, and said he had been the subject of a large rupture on the right side for the last fifteen years, and that on two occasions during the last two years it had become temporarily irreducible after unusual exertion, the irreducibility being accompanied by vomiting and constipation, but he was relieved by rest and opium, followed by taxis. With these exceptions the rupture had always been easily reducible. His medical attendant, who brought him to the infirmary, gave the following history of his present seizure. On June 27th (eight days before admission) he was suddenly attacked by a severe pain in the right groin whilst gardening, the hernia being down at the time. He reduced it without using more than customary force, and without observing anything unusual in its condition, either before or during reduction. But the pain was not relieved, and vomiting shortly afterwards set in, whereupon he sent for his doctor, who upon examination could make out nothing except an empty hernial sac occupying the right side of the scrotum and the inguinal canal. A dose of morphia was administered, which entirely relieved the symptoms, and the patient remained at work in apparent health until July 2nd, when there was a recurrence of pain and vomiting, which were again relieved by morphia. During this interval the hernia had not been perceptible. On July 3rd the symptoms again recurred, and a little fulness was detected in the region of the internal abdominal ring, which, however, disappeared under manipulation, and he felt easier. The bowels not having acted, an enema was given, which produced a scanty scybalous evacuation. At midday on the 4th he felt quite well, and a dose of castor oil was administered. At 5 P.M. he was again attacked with pain and vomiting. At 9 P.M. the localised fulness in the abdomen was again perceptible, but gentle massage caused its disappearance, together with the symptoms, which remained in total abeyance until 3 A.M. the following day, when they returned with marked aggravation, and he was brought to the infirmary, experiencing another complete remission before he arrived.

"On admission the man complained only of a little uneasiness, scarcely amounting to pain, which he referred somewhat vaguely to the right iliac fossa. Otherwise he seemed in good condition, presenting a bright and cheerful aspect, with a fresh colour, and cool, comfortable skin; pulse and respiration tranquil and natural. The tongue was slightly furred in the centre, but there was no vomiting, which had ceased an hour before. There had been no passage of fæces or flatus for two days. The abdomen was examined, with negative results. There was no distension or tenderness, neither could any abnormal masses or unusual resistance be detected anywhere, and the respiratory movements were full and free. The scrotum was very lax, and the right side was occupied by an empty hernial sac, which extended almost as low as the testis. Upon invaginating the scrotum and sac, the tip of the finger could be easily pushed through the inguinal canal to a point within the abdominal cavity, quite an inch beyond the internal ring. The rings and canal were much enlarged and free from obstruction, and no indication of hernia, tumour, or resistance of any kind could be detected within the abdomen. There was no other external hernia. Rectal examination revealed a slight fulness in the pelvis on the right side, but of so indefinite a character that little importance was attached to it, even in face of the fairly reasonable assumption of reduction *en masse*. In the total abeyance of symptoms, and having regard to the good general condition of the patient, operative interference was discarded as unjustifiable for the time being; but during the afternoon vomiting came on again, grew steadily worse, and towards evening became distinctly stercoraceous. Mr. Ward was again summoned, and decided to perform an exploratory laparotomy.

"Under ether, and with full antiseptic precautions, a median vertical incision about two inches in length was made midway between the umbilicus and pubes. Upon introducing a finger, the condition of things was at once recognised. Tracing the parietal peritoneum towards the inguinal region, the finger was arrested about two inches from the internal abdominal ring, at a point in line with it and the umbilicus. Here it was found that a portion of small intestine passed through an aperture about large enough to admit the index finger, and presenting a thickened tough margin. Judging by the amount of included mesentery, a considerable length of bowel had passed through the opening, and it was firmly held. The parietal peritoneum was obviously extensively stripped, for this constricting ring could be moved freely for a considerable distance in all directions, and, in fact, could be brought within view at the abdominal wound without much tension or any further stripping. Extending towards the pelvis, beneath the peritoneum, was a soft, rounded swelling about the size of an orange. An attempt was now made to withdraw the intestine by traction, but this was found to be impossible. The stricture was therefore freely divided, and then, with some little difficulty, the bowel was slowly teased out of its prison. It was swollen and deepened in colour, but of good polish and in sound condition. On further examination, it was found that when the finger was introduced into the mouth and neck of the sac it could be passed in two directions: on the outer side along the inguinal canal, lined by peritoneum; and on the inner side, through a rent in the neck of the sac, into an irregular cavity, limited on the one side by the outer surface of the stripped peritoneum, and on the other by the pelvic fascia, and it was into this cavity that the intestine had been displaced. It was laid open from end to end by a prolongation of the former incision. This was done in order to minimise the risk of further entanglement. After ascertaining that there was no hæmorrhage, the abdominal incision was closed by means of three deep sutures of wire, with intermediate ones of catgut, and an antiseptic dressing was applied.

"The subsequent history may be summarised as follows: The symptoms were at once relieved; flatus passed almost immediately after the operation; the bowels acted freely and spontaneously on the second day; and the temperature remained normal throughout. The wound was found to be healed, and the sutures were removed at the first dressing, which was on the fifth day. On the ninth day the patient was up and ready to go home, but was detained for the adjustment of a suitable truss. He went home on July 18th."

A noticeable feature in the history of the case was its close resemblance in every point to the classical descriptions of this condition: an oblique inguinal hernia of long standing; the patient in the habit of reducing it himself; the hernia reduced by the patient at the time of the accident, without anything unusual being noticed; and subsequently the irregularity, and for a time the comparative mildness, of the symptoms, with prolonged intermissions. I believe that it is next to impossible for reduction *en masse* to occur under the taxis of a surgeon who has been instructed in the merest rudiments of his art; and that it is always caused by forcible squeezing, and pushing and kneading over the fundus of the tumour, without any steadying or support of its neck; and after frequently observing patients go through this performance by way of demonstrating how a hernia should *not* be reduced, my chief wonder is that, displacement being possible, it is not an occurrence of much greater frequency.

With regard to the operation, it appears to me that the arguments in favour of a median abdominal incision infinitely outweigh any that can be urged against it. It makes the operation simple, easy, precise, and safe. There is no danger of wounding any large vessels or important anatomical structure; the trifling hæmorrhage is within view and absolutely under control; the diagnosis is either verified or negatived at once without difficulty, and if it should prove to have been at fault the abdominal cavity may be thoroughly explored for other causes of obstruction; besides this, the constricting band is much more easily reached and divided. Luke's description of the operation, which he performed almost half a century ago, is practically copied into all the modern text-books, and a few extracts from it may illustrate its disadvantages: "An opening between three and four inches in extent was made.....The canal was next laid open by a division of the tendon of the external oblique muscle.....freely dividing the margin of the internal ring.....The sac should in all instances be opened, and its neck freely divided.....The extensive division of the abdominal parietes rendered extra precautions necessary against reprotrusion of the intestines."

But it is argued that this exploratory operation does not necessarily involve incision of the peritoneum before reduction *en masse* can be negatived. This may be true, but in that case what is gained? The patient has been subjected to an operation which in itself is not devoid of danger, which must necessarily reduce his powers, which has advanced the agnosis by a mere fragment of negative

evidence, and which has left him unrelieved. What then, surgically speaking, remains? Laparotomy. If, however, a displaced hernia should be found, it can only be relieved by a peritoneal section in a situation where its risks are greater and its management more difficult. It may be said against laparotomy that it precludes any attempt at radical cure; but this, under such circumstances, is surely a minor consideration; and it is interesting to notice that the patient whose case is described above has not yet been troubled by any reappearance of his hernia. If the gut should be gangrenous, opening the sac into the general peritoneal cavity would appear to mean certain death from septic peritonitis; but we have apparently not yet thoroughly explored the resources of antiseptics, peritoneal irrigation, and enterorrhaphy; and I am not aware that there is any case on record in which a patient suffering from displaced hernia in which gangrene had supervened has ever recovered under any method of treatment.

Leeds.

THE

DISTRIBUTION OF PYÆMIC ABSCESSES.

BY STEPHEN PAGET, F.R.C.S.

IN THE LANCET of April 17th I published sixty cases of that form of parotitis which is secondary to some abdominal or pelvic lesion. This parotitis is very seldom accompanied by any other similar lesion; it is not evidence of true pyæmia, and it usually ends in recovery. There is reason for thinking that its connexion with the abdomen and pelvis is due to the lymphatic system.

Wishing next to see whether, in true pyæmia, the distribution of the secondary lesions is in any way related to the site and nature of the primary lesion, I analysed more than 500 recorded cases of pyæmia. They show clearly that the distribution of abscesses in pyæmia is not merely a matter of chance. Thus, abscess of the liver is related to fracture or section of a bone; pleurisy and pericarditis are more common after injuries of the limbs than after injuries of the head or of the trunk; certain lesions are plainly grouped together in certain sets of cases. It is hard to see how these facts could be explained as mere results of embolism. In all embolism, the emboli, wherever they are first formed, must all start fair again from the heart, after passing through the lung-capillaries; all have exactly the same chance of being lodged in this or that particular organ. If, then, the distribution of pyæmic abscesses is not haphazard, but subject to certain rules and combinations, these abscesses must be due, not to septic embolism alone, but to something else as well. This "something else" is probably a certain state of the tissues themselves, or of the lymphatic system. Perhaps pyæmia may here be compared to syphilis; in syphilis there is the constitutional disease, and also a special liability of certain tissues to the disease, and a special state of the lymphatics, shown by the general glandular enlargement. So in pyæmia, the state of the tissues themselves, and of the lymphatics, may work together with septic embolism in producing suppuration.

The importance of the lymphatics in pyæmia is well shown in Dr. Tilt's paper on "Lymphangitis in Pelvic Pathology" (Obstetrical Society, xvi.). It is easy among my 500 cases to pick out many where the serous and synovial membranes, which are really parts of the lymphatic system, have borne the whole brunt of the disease. Perhaps their importance may show itself if we take the questions which most naturally suggest themselves as to the pathology of the disease, and consider them with the help of the tabulated cases.

I. In pyæmia, does previous disease or weakness of any organ make it more liable to abscess? Thus Guthrie says: "I conceive the viscera in each person most predisposed to disease will be the most likely to be affected." Travers says: "In a person of phthisical diathesis the weight of the injury would fall upon the lungs, whereas in one subject to hepatic congestion it would probably fall upon the organs included in the system of the vena porta." And Lawrence says much the same. Evidence is not easily found in support of these views, but there *is* some evidence that a simple fracture or subcutaneous injury is likely to suppurate if the poison of pyæmia gets at it. This was shown by the experiments of Chauveau, Loeffler, and others, and by the following cases:—

1. Primary amputation of right thigh. Pyæmia; death. Post-mortem: "Une fracture de la côte, dont le malade ne s'était aucunement plaint. Le foyer de la fracture est rempli de pus louable et sans odeur." (Sédillot.)
2. Amputation of thigh. Pyæmia; death. Post-mortem: "The fourth rib was found fractured, and a small quantity of pus external to the pleura costalis." (Balfour.)
3. Fracture of both legs and of sternum: Amputation of right leg. Pyæmia; death. Post-mortem: "Left saphena vein full of pus; fracture of sternum bathed in dirty pus." (Path. Soc., xxx.)
4. Scalp wound with fractured skull; fracture of sternum. Pyæmia; death. Post-mortem: "Suppuration in portions of the fractured sternum." (Wilks.)
5. Compound fracture of right leg; fracture of humerus and of ribs. Amputation of leg; death. Post-mortem: "Suppuration round the fractured humerus; no visceral abscesses." (Wilks.)
6. Fracture of lower jaw. Pyæmia; death. Post-mortem: "Suppuration round simple fractures of thigh, humerus, and ribs." (Path. Soc., xxx.)
7. Venesection; phlebitis. Pyæmia; death. "A large abscess formed rapidly in the leg, at the spot where the patient had received a trivial injury just before the venesection." (Castelnau and Ducrest.)

II. Is there such a thing as a predisposition to pyæmia? Dr. Moxon says, "There must be something very special in the constitution of the person." But Braidwood says, "The majority of the victims are the healthiest of our race." Certainly, in some cases the rapidity and extent of the suppuration are astonishing: they seem to run to abscesses, to have a real "prédisposition à la purulence." Yet this may be due to some admixture of pyæmia with scrofula. Mr. Hewett's case is interesting here: A gentleman who recovered from pyæmia after tonsillitis died, four years later, from pyæmia after removal of a wart.

III. Is pyæmia from a slight wound worse than from a bad one? Mr. Bryant says: "After trivial accidents the pathological results were far more severe than after grave accidents. Suppuration involved a larger number of glands as the liver, the kidneys, the spleen, and the heart." Dr. Chevers says much the same. My cases show a different result, as follows:—

		Liver.	Spleen.	Kidneys.
Severe injury of a limb, such as amputation, excision, compd. fracture (195 cases).	Marked disease	55	29	13
	Congestion &c.	15	19	14
Slight injury of a limb, such as venesection, or dissection wound, or whitlow (45 cases).	Marked disease	1	1	0
	Congestion &c.	0	2	1

This is roughly reckoned; but it is evidently opposed to the view taken by Mr. Bryant.

IV. The state of the heart in pyæmia. Dr. Wilks says of his large collection of cases: "In several cases it will be seen that the heart has been affected by purulent deposits; and it will be noticed that this occurred only in the very worst forms of the disease, and especially where a diffused abscess in a limb had been the source of the mischief." The heart is a muscle; and some muscles are more liable to pyæmic abscess than others. But perhaps it is not safe to argue from other muscles to the "musculus nobilissimus." The 500 cases appear to show that true abscess of the heart in pyæmia is most common after some lesion of the lower limb. Thus, in 97 cases of pyæmia from some genito-urinary lesion, not one had true abscess of the heart. One had purulent infiltration of the mitral valve; one had mottling of the heart, with softening patches; six had ecchymosis of the heart. But ecchymosis may proceed from very different causes—as from poisoning by strychnia, &c. In 77 cases of pyæmia from some lesion of the head or neck, 3 had true abscess, 3 had ulcerated valves, and 3 had ecchymosis. In 96 cases of pyæmia from lesion of the upper limb, 4 had true abscess, 1 had myocarditis, and 4 had ecchymosis. In 243 cases of pyæmia from lesion of the lower limb, no less than 21 had true abscess, 2 myocarditis, 4 ulcerated valves, and 9 ecchymosis. Thus abscess of the heart wall seems to be most common in pyæmia when the primary lesion is of the lower limb. The primary lesion was not, in all the cases, severe: in one it was a sore on the heel; in another it was a

scratch on the foot. It is certain that pyæmia which starts from the lower limb does, as a rule, have a severe course, affecting many organs and many joints. Perhaps this fact is related to the fact that pyæmia does, to begin with, choose wounds of the lower limbs for its primary seat more often than wounds of any other part. Thus, in the American war, the statistics were as follows:—

After wounds of the lower limb, pyæmia occurred in			18·1	per 1000
,,	,, upper limb,	,,	10·4	,,
,,	,, trunk	,,	6·9	,,
,,	,, head and neck	,,	2·5	,,

It seems natural that the poison which has entered the body at its favourite site should act with the full measure of its severity.

V. In pyæmia, is the inflammation of the serous membranes due merely to extension of inflammation from the viscera underneath? Thus Dr. Wilks says, "Inflammations of the serous membranes are altogether secondary to the inflammation of the tissues which the serous membrane covers." And Sédillot says much the same. It is hard to see why pleurisy and pericarditis in pyæmia should not be independent of pneumonia and myocarditis, just as the effusions into the joints are independent of the heads of the bones, or just as ordinary pleurisy and pericarditis are independent of pneumonia and myocarditis. Cases are not rare where there are large effusions into the pleuræ, but nothing wrong noticed in the lungs; and where there is pericarditis, but nothing wrong noticed in the heart. My 500 cases give the following figures:—

Cases of heart disease, no mention of pericardial disease ...	35
Cases of pericardial disease, no mention of heart disease ...	31
Cases where both heart and pericardium were diseased ...	25
Cases of lung disease, no mention of pleura	202
Cases of pleural disease, no mention of lungs	21
Cases where both lungs and pleuræ were diseased	191

Of course there are cases where the serous inflammations do result only from underlying inflammation, and are proportionate to it. But the following cases show that serous inflammations in pyæmia may occur separately:

1. Wrist disease (male, aged forty-three). Post-mortem: Lungs healthy. In the right pleura two pints and a half of semi-purulent fluid; in the left pleura three pints. Pus in right knee. Spleen dark and soft. Veins healthy. (Path. Soc., xxx.)
2. Chilblains on fingers, phlebitis (female, aged thirty-six). Post-mortem: Pleurisy same side; bloody fluid in pericardium; serous meningitis. (Ribes.)
3. Injury to hip-joint at birth; death in seven days. Post-mortem: Pleura on same side filled with pus; abscess over wrist. (*Med. Times and Gaz.*, 1863.)
4. Purulent otitis. Post-mortem: A pound of puriform fluid in the opposite pleura; the lung collapsed. (Abercrombie.)
5. Purulent otitis (male, aged thirty). Post-mortem: Pleurisy on same side; pericarditis; peritonitis; abscess in opposite lung; abscesses in liver. (R. Reynolds, "System of Medicine.")
6. Dissection wound of finger. Post-mortem: Lungs congested; eight ounces of bloody fluid in each pleura; serum in pericardium; serous meningitis. Pus on knee in same side; ecchymoses of kidneys and intestines. (Travers.)

There are many more cases like these. Pleurisy, pericarditis, and meningitis seem to group themselves together, and to occur in association with effusions into the joints and into the synovial sheaths of the tendons, rather than with visceral abscesses.

VI. The favourite sites of abscess in pyæmia. First, of course, the lungs. Next, among the muscles, the pectorals and the calf muscles suffer most often—about one case in thirty. Abscess of the pectoral muscle appears in some cases to be due to the spread of suppuration from the axilla or neck, or from around the shoulder-joint or the sterno-clavicular joint. But in others it seems to begin in the muscle, or between the major and the minor, or beneath both. The following cases show this:—

1. Gonorrhœa (male, aged twenty-two). Effusions into various joints; pericarditis; large abscess in pectoral region, involving shoulder-joint. (St. Barthol. Hosp. Reports, vol. iii.)
2. Fractured base (male, aged fifty-four). Abscesses in liver and kidneys; an enormous abscess under the pectoral muscle. (Lebert.)
3. Venesection of right arm; purulent clot in vein. Lungs hepatised; pleurisy; meningitis; thick greenish pus in interfibrillar tissue of right pectoral muscle. (Arnott.)
4. Gangrene of left leg after old gunshot wound; pus in veins. Abscess, apex of left lung; meningitis; large abscess under pectoralis major. (Ribes.)
5. Necrosis of left femur. Large abscess in course of pectoral muscles. (Guthrie.)
6. Necrosis of left femur. Lungs, heart, and kidney all diseased. Abscesses in the pectoral muscles. Path. Soc. xxx.)
7. Amputation of left great toe (male, aged forty-one). Pus in veins. Abscesses in lungs; an enormous abscess under left pectoral, passing down into axilla. (Sédillot.)

I have notes of fourteen or fifteen cases of this kind of abscess.

Abscess of the calf seems to begin in or near the soleus. It is to be observed that in three-fourths of the cases where it occurred there was also suppuration in one or both of the upper limbs. Among sixteen or eighteen cases are the following:—

1. Puerperal fever. Abscess of left axilla; abscess of left calf; destructive suppuration of left eye. (Marshall Hall.)
2. Injury of vagina; erysipelas. Abscesses over shoulder, in elbow, and in each calf; superficial abscesses elsewhere. (*Med. Times and Gaz.*, 1863.)
3. Scalp-wound with fracture. Abscesses of liver, lungs, and abdominal wall; large abscess in arm; large abscess in leg. (Wilks.)
4. Amputation of right thigh. Abscess under left soleus, close to interosseous ligament. (Guthrie.)
5. Amputation of left foot. Abscesses of left lung; abscess near right elbow; abscess in right calf. (Wilks.)
6. Excision of varicose vein, right leg. Abscess of right lung; meningitis; inflammation of both eyes; intramuscular abscesses in both forearms; deep abscess in left leg. (Arnott.)

Another favourite site of abscess in pyæmia is the back of the hand. This abscess is not due to suppuration in the wrist-joint or in the finger-joints; it seems to begin in or around the synovial sheaths of the extensor tendons. I have notes of 16 cases, and it is interesting that 12 were on the left hand and only 4 on the right. Of these 16, one or two were not "abscesses," but "pustules" or "vesicles"; still, I venture to include them. There is some reason for thinking that this abscess at the back of the hand is related to the state of the lymphatic system. It is in relation to a synovial membrane, and in a part of the body where the lymph spaces are extraordinarily large; it is found along with other synovial and serous effusions rather than with visceral abscesses; it seems, by its preference for the left hand, to be not merely due to haphazard embolism; and, lastly, it seems, like parotitis, to be in some way influenced by the site of the primary lesion. In one very interesting case of chorea, ending fatally, in which I made a post-mortem, I found double parotid abscess, and one at the back of the left hand, and no other evidence of pyæmia. The following are also interesting examples of this lesion:—

1. Delivery; endometritis. Abscess at back of left hand, with sloughing; pus up the forearm; no trace of disease in bloodvessels. (Lee.)
2. Delivery; abscess in lung; meningitis. Abscess in extensor sheaths of both hands. A case of lymphangitis. (Tilt.)
3. Cystotomy for a foreign body. Both knees full of pus; pus in left elbow and in sheaths of extensor tendons of left hand. (Path. Soc., xxx.)
4. Removal of part of right clavicle; pleurisy; pericarditis. Pus in left sterno-clavicular joint; pus in sheaths of left extensor tendons. Veins normal. (THE LANCET, 1864.)
5. Fracture of right ulna. Abscesses in lungs and in liver; pericarditis; meningitis; pus in right elbow and shoulder; abscess at back of left hand. (Amer. War, vol. iii.)
6. Wound of right finger; purulent infiltration of right arm; veins diseased. Abscess of left lung; pericarditis; abscess at back of left hand. (Amer. War.)

There is one more special lesion of great interest—inflammation of the eyeball. I have notes of 18 cases. Like the

inflammation of the back of the hand, it shows a marked preference for the left side over the right; like it, a very large proportion of the cases have followed uterine disease. These facts, with what we know of parotitis, may make us inclined to think that septic embolism alone does not fully explain this lesion. This ophthalmitis must be distinguished both from phlegmonous inflammation of the orbital cellular tissue and from inflammation extending into the orbit from the base of the brain. It is true inflammation of the globe itself, with subretinal effusion and purulent infiltration of the vitreous. It is beautifully described in Bowman's "Diseases of the Eye." The best examples are Marshall Hall's six cases after delivery, all of the left eye; also the following:—

1. Mrs. E—— (aged thirty-five). Three weeks after delivery, right phlegmasia dolens; three weeks later, pyæmia, with destructive inflammation of both eyes. Post-mortem: Pus in left lung; two pints of purulent fluid in left pleura; plugging of veins of limb.
2. Mrs. —— (aged thirty). Delivery; peritonitis. Inflammation of left eye. No post-mortem. (Mackenzie.)
3. Mrs. ——. Delivery: adherent placenta. Meningitis; inflammation of right eye. (Mackenzie.)
4. Arnott's case, quoted above.
5. Venesection for pleurisy (male, aged thirty-five). Meningitis; destructive inflammation of both eyes. (Mackenzie.)
6. Abscess in right leg (male, aged eighteen). Swollen and painful joints; pus in left knee. Destructive left ophthalmia; pus round both globes, especially left. Sinuses healthy. (Wilks.)

Admirable descriptions of this lesion are to be read in the *Archives of Ophthalmology*, vols. ix. and xi. There is abundant evidence that septic embolism may cause it, but I venture to think that the state of the eye itself, or of the lymphatic system, may in some of the cases co-operate with the work of embolism and predispose the eye to suppuration.

VII. Section of the bones, as influencing the production of abscess of the liver. I was struck by finding how much more common abscess in the liver is, after division of the bones of limbs, than after other injuries. Sédillot says: "Nous avons été frappés d'une sorte de coincidence entre les suppurations du foie et les altérations du système osseux chez beaucoup de nos pyoémiques. Un vénérien, atteint d'une ostéite du pubis avec infection purulente, avait des abcès du foie: plusieurs amputés, dont les os étaient malades, nous offrirent les mêmes lésions." My tables run as follows:—

		Abscess (not counting congestion &c.)		
		Liver.	Spleen.	Kidneys.
Injury or disease of medulla.	Upper limb (52 cases).	20	8	2
	Lower limb (165 cases).	36	20	4
Necrosis, in most cases acute.	Upper limb (4 cases).	0	1	3
	Lower limb (34 cases).	2	4	14
Suppurative arthritis.	Upper limb (2 cases).	0	0	0
	Lower limb (17 cases).	4	3	5
Injury or disease of soft parts only.	Upper limb (40 cases).	4	0	3
	Lower limb (22 cases).	0	3	5

Putting the two limbs together, we have—

	Abscess (not counting congestion &c.)		
	Liver.	Spleen.	Kidneys.
Injury or disease of medulla: amputation, compound fracture, caries (217 cases)	56	[illegible]	6
Necrosis (38 cases)	2	5	17
Suppurative arthritis (19 cases)	4	3	5
Injury or disease of soft parts only (66 cases)	4	3	8

This seems to prove that abscess of the liver and of the spleen is promoted, in pyæmia, by injury or disease of the medulla of the bones. Now, the medulla of bones is part and parcel of the lymphatic system, and so is the spleen. Do we not see here another instance of the influence of the lymphatic system in the distribution of pyæmic abscesses? The association of abscess of the kidneys with acute necrosis is also important.

ON TINNITUS AURIUM AND ITS TREATMENT BY ELECTRICITY.

By JULIUS ALTHAUS, M.D., M.R.C.P.,
SENIOR PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

TINNITUS AURIUM, when loud and continuous, is one of the most distressing affections, and apt to greatly depress the tone of the mind and of the whole nervous system of the patient. St. John Roosa[1] mentions the case of a gentleman who consulted him for it, and received an unfavourable opinion as to recovery; and who thereupon said that, if he thought it correct, he would put an end to his existence which he did a few months afterwards by blowing out his brains! The same author speaks of another patient who committed suicide on account of this symptom; and most practitioners must have met with cases in which all enjoyment of life has been destroyed, the patient's temper soured, and his power of work greatly reduced, through tinnitus. This symptom is probably always produced by increased pressure on the labyrinth, and therefore occurs in a variety of affections of the external, middle, and internal ear, and in the neighbourhood, giving rise to this undue pressure. Sir William Dalby[2] says that, when it is due to some curable local cause, it rapidly disappears with its removal; but that when it accompanies deafness in nervous affections, it is often the more troublesome symptom of the two, and less amenable to treatment.

The fact that we are able, by a judicious and careful application of electricity, to cure or relieve a considerable proportion of this latter class of cases, where there is no coarse lesion giving rise to the undue pressure, but where this latter is probably owing to disturbed vaso-motor influence, is either ignored or doubted in most of the best works on aural diseases. This unfavourable opinion of the authorities is undoubtedly owing to the circumstance that there is perhaps no other complaint the successful treatment of which by means of electricity requires so much special knowledge of the physiological effects of that agent, such delicate adjustment of apparatus, and such technical skill in manipulating the same, as tinnitus of nervous origin; while, on the other hand, a haphazard application of electricity, even by those who are tolerably well acquainted with the other more common uses of the battery, is likely to do rather harm than good, and the chance of thereby accomplishing a cure must be considered as exceedingly remote. I do not intend in this paper to give an account of the researches of Brenner, Hagen, Moos, Erb, and others, which have opened up this subject, but proceed at once to the narration of a well-marked case of tinnitus of vaso-motor origin which was recently under my care, and in which the beneficial influence of a carefully adjusted electric treatment was strikingly displayed.

S. N——, a merchant, aged thirty-five, married, and father of two children, consulted me in October last, and informed me that about two years ago he had, in consequence of unusually hard work and great anxiety in business, got into a low state of health, with dyspepsia, constipation of the bowels, and considerable mental depression. While in this condition he heard one morning, on awakening, a curious noise in his left ear as if a kettle was boiling there, and had a feeling of giddiness on changing the position of his head. The noise continued, and in the course of a few days became much louder, so as to resemble the breaking of the waves on the sea-shore, and the hearing of the same ear became much impaired. The patient was treated with alteratives, strychnia, iodide and bromide of potassium, &c., and was eventually advised to take a long holiday. From this he returned rather better, but after having been in business again for a few days the trouble returned worse than before. Further treatment did not improve the condition, and matters at last began to assume a serious aspect, inasmuch as the patient's power of application was very much diminished, his confidence in himself almost gone, and the irritability of his temper so extreme that his family as well as his associates in business found the greatest difficulty in bearing with him. Under these circumstances the question was mooted whether he should not give up business, at least for

[1] The Diseases of the Ear (London, 1885), p. 344.
[2] Quain's Dictionary of Medicine (London, 1882), p. 1636.

a time, and take a voyage to Australia; and it was chiefly with regard to this latter point that I was eventually consulted.

On examination, the patient had a sallow complexion, an anxious expression, a pale tremulous tongue, and a feeble pulse. He answered questions in a hasty, abrupt manner, stated that he had lost all confidence in his powers, and complained bitterly of the dreadful trouble caused to him by the noise in the head, which was incessant throughout the day. He described it as the roaring of the breakers on the seashore. He felt giddy whenever he turned his head quickly round, stooped, or blew his nose. There was a decided degree of deafness of the left ear, where the ticking of a watch could not be perceived, while the tuning-fork was only very dimly heard when held close to the meatus. With the right ear the same watch was quite plainly heard, and the tuning-fork at a distance of three inches and a half.

I now proceeded to the galvanic examination of the auditory nerve, according to Brenner's method as modified by Erb, which gave the following results:—

1. *Current-strength:* 1½ *milliampères.*

Right ear.	Left ear.
Ca Cl[3] no sound	Tinnitus increased.
Ca Sta „	Ditto.
Ca O „	As before.
An Cl „	Diminished.
An Sta „	Ditto.
An O „	As before.

2. *Current-strength:* 3 *milliampères.*

Right ear.	Left ear.
Ca Cl produces a short hissing sound, other arrangements being ineffectual.	Same qualitative reaction as in 1, but effect of Ca Cl and An Sta much more marked.

3. *Current-strength:* 5 *milliampères.*

Right ear.	Left ear.
Ca Cl gives a strong hissing sound, An O a slighter do.; other arrangements ineffectual; fulness in head and giddiness in closing and opening.	Same reaction as in 2, except that with An Sta the tinnitus is almost entirely stilled, and that the patient can only just hear it by giving the closest attention, as if it were occurring at a considerable distance.

It appeared from this that the healthy right ear gave the normal galvanic formula of the auditory nerve, while, on the contrary, in the affected left ear that condition was found which Brenner has described as simple galvanic hyperæsthesia of the auditory nerve, in which there is exaggerated response to Ca Cl, Ca Sta, and An O; while An Cl and An Sta tend to still the noise. These galvanic tests seem to show that there is no coarse lesion in the different portions of the ear or its neighbourhood, as tinnitus owing to such is apparently uninfluenced by the application of electricity.

Having discovered that the stationary action of the anode arrested the noise almost completely for the time being, I gave a favourable prognosis, and advised a course of galvanic treatment, which was carried out in the following manner. A well-moistened medium-sized anode was placed on the left external meatus, and a similar cathode on the palm of the right hand; a current of five milliampères was used, and allowed to pass for five minutes. During this time the tinnitus gradually diminished, and eventually ceased altogether. The current was then, by the aid of the rheostat, gradually reduced in strength; but when it had been diminished by the interpolation of fifteen resistances, the tinnitus suddenly started afresh, and I therefore found it necessary to increase the galvanic force again for obtaining another cessation of the noise. This was accomplished in two minutes, and the same strength was then allowed to act for another minute. After this the current was very gradually reduced by the successive interpolation of fifty-one resistances. In this way the prejudicial effect of the anode opening, which causes increase of tinnitus in ordinary hyperæsthesia of the auditory nerve, was as much as possible circumvented. The whole application lasted about twenty minutes, was unattended by pain or giddiness, and at the end of it the tinnitus had entirely disappeared. At his next visit the patient informed me that the noise had only been in abeyance for an hour, that it had then returned, and the day after been much the same as before. A second application, on the same lines as the first, arrested the tinnitus again, and, with the exception of a singular sensation as if some bubbles were bursting in his ear, the next day was passed very comfortably. The patient felt in the best of spirits, could eat his meals with relish, had more confidence in his powers, and slept well. About ten days afterwards, after an unusually hard day's work, the noise reappeared for a short time, but had ceased of itself next morning. The patient had altogether nine applications of electricity, after which he felt so well that there appeared to be no need for further treatment. I have recently heard that there has been no return of the tinnitus and vertigo, and that the hearing of the left ear was likewise much improved.

There is another class of cases of tinnitus in which Brenner has shown that the normal response of the auditory nerve to the continuous current is reversed—that is to say, the anode, instead of diminishing the noise, increases it, while the stationary cathode tends to arrest it. Cases also occur in which various other deviations from the normal formula take place, into which space prevents me from entering here. The chief rule for treatment must be to utilise that arrangement for treatment which is found effectual in arresting the noise, regard being had at the same time to a gradual reduction of current-strength, and, if necessary, a fresh increase after diminution. It is therefore of paramount importance not to proceed by routine, but to ascertain as accurately as possible the physiological response of the suffering nerve to the voltaic current in each individual case of tinnitus of vaso-motor origin previous to the beginning of a galvanic treatment.

Harley-street.

[3] Ca Cl = Cathode closing; Ca Sta = Cathode stationary; Ca O = Cathode opening; An Cl = Anode closing; An Sta = Anode stationary; An O = Anode opening.

CHILDBED FEVER; ITS CAUSES AND PREVENTION: A LIFE'S HISTORY.

By THEODORE DUKA, M.D., F.R.C.S.Eng.

THE name of Semmelweis was brought to notice in England by an article in the Transactions of the Royal Medical and Chirurgical Society for 1849. Dr. Routh, its author, was then fresh from Vienna, and gave a concise account of what he had seen there. Semmelweis's labours have been frequently spoken of since in medical literature, both in the English press and on the Continent, but a full sketch of his life and studies has only now been supplied in an elaborate monograph by Dr. Jacob Bruck, a member of the Board of Health at Buda-Pesth. To my mind it forms a most interesting piece of medical study—indeed, it belongs to the epoch-making productions of medical history.

Ignatius Philippus Semmelweis, a Hungarian, was born on July 17th, 1818, in the city of Buda, where his father was engaged in mercantile pursuits. There were four brothers, of whom Ignatius was the youngest. At the age of nineteen, when entering as an undergraduate at the University of Vienna, his parents urged Semmelweis to study law, but after hearing a lecture on anatomy, to which he was accidentally invited by a young friend, Semmelweis decided to abandon law and to devote himself to the study of medicine. The Vienna school was becoming famous, at that time under Professors Rokitansky, Skoda, and Hebra, who spread the fame of the Imperial University far and wide. His first year of study was spent at Vienna, the second and third at the University of Pesth; for the remaining two years Semmelweis returned to Vienna, where he graduated as Doctor of Medicine on April 4th, 1844, taking for his thesis "De Vita Plantarum." In two years more he obtained diplomas in midwifery and as Doctor in Surgery. Semmelweis's time and energies were henceforth entirely devoted to medicine. Having previously attracted the notice of Skoda and Rokitansky as an intelligent, industrious, and energetic student, they now honoured him with their friendship and goodwill. Skoda, in particular, took a prominent part in encouraging Semmelweis in his investigations, and Rokitansky's pathological laboratory was opened to him. For some time Semmelweis remained undecided as to what special branch he would pursue; he ultimately selected diseases of women, but not until his

cherished hopes of becoming Skoda's assistant had been frustrated. To this coveted post Dr. Löbl was appointed, who in consequence of seniority had a preferential claim. Professor Klein was at that time at the head of the maternity department, and in June, 1844, Semmelweis applied for an assistant's appointment in the women's clinique. In the early part of 1846 he was thus appointed on probation for six months, at the expiration of which period he was confirmed in his office as regular assistant professor in the maternity branch. In this way Semmelweis became one of the staff in the General Hospital at Vienna. This gigantic institution was built by the Emperor Joseph and opened in 1784, the maternity department being then placed under Dr. Simon Zeller. In 1789 the famed Dr. Boër succeeded, and continued in his appointment for a period of thirty-three years. During the first thirty-nine years of its existence there were 71,395 admissions into the maternity, with 897 casualties, giving a death-rate of 1·25. Alarming outbreaks of puerperal fever seldom occurred during this period, but when they did occur, Professor Späth tells us, they caused intense anxiety and vexation to Dr. Boër; yet the insignificance of these attacks may be compared, says Semmelweis, to small hillocks, because "the hecatombs which were later witnessed stand forth like a Chimborazo." And truly alarming became the records of mortality under Professor Klein; the ratio was hardly ever under 5·03, and sometimes rose as high as 7·45. No change was effected in these unfavourable returns, when a new wing was opened, into which Dr. Klein's patients had been transferred. Among the epidemic outbreaks causing great havoc among the child-bearing women at the hospital, the most fatal was that which occurred in October, 1841, lasting without intermission for twenty months—that is, till May, 1843. Of 5139 parturient women 829 died, giving the terrible death-rate of more than 16 per cent. Moreover, these numbers did not entirely represent the magnitude of the actual mortality, because they do not comprise those cases which had been transferred to the physicians' wards owing to complications. The mortality of the newborn infants was in proportion to that of the mothers.

The Clinique No. 1 was under Dr. Klein; No. 2 was under the care of Dr. Bartsch. In both instruction was imparted to students and midwives, and there was no marked difference in the death-rate; but after the Government decided that Dr. Klein's clinique should be apportioned to students and that of Dr. Bartsch to midwives exclusively, a change in the returns became very apparent. During six years—viz., from 1841 to 1846 inclusive—the mortality in the students' clinique stood at 9·29; in that of the midwives at 3·38 only. The great fatality in the students' clinique, therefore, attracted the early notice not only of the Director but of the University professors, and eventually of the Government also. One commission of inquiry followed another, but none could exactly determine the cause of the high rate of mortality. All kinds of explanation were given and recommendations made, which led, however, to no satisfactory results. Among other things, a special objection was taken to foreign students, whose number had, in consequence, been reduced from forty-two to twenty. Some of the measures adopted only proved of temporary avail, and the bad name of Dr. Klein's clinique spread to such an extent that, according to Semmelweis's statement, patients, on finding themselves among the inmates of the dreaded clinique, fell on their knees, and with clasped hands begged to be allowed to return to their homes. Occurrences like these made a profound impression, and the sound of bells which used to be rung in the wards when the priest was administering the last sacrament to the dying—a circumstance unfortunately of almost daily occurrence,—told with increasing effect on the sensitive mind of Semmelweis. "I myself was terror-stricken" (these are his words); "when I heard the sound of the bells at my door a deep sigh rose in my breast for the unfortunate mother, who was the victim to a cause hitherto unknown; this worked on me as a fresh incentive that I should, to the best of my ability, endeavour to discover the mysterious agent, and a conviction grew day by day that the prevailing fatality in the Clinique No. 1 could in nowise be accounted for by the hitherto adopted etiology of puerperal fevers."

Experience and common sense alike precluded the view that the alarming death-rate was solely due to "atmospheric, cosmic, or telluric influences." Semmelweis therefore put the question to himself: In what manner can any circumstance be brought in connexion with the unknown cause, which acts so disastrously in the Clinique No. 1, whilst in the Clinique No. 2 the puerperæ are so much more favourably circumstanced? He saw that if the fatality had depended on atmospheric changes merely, the fatal fever ought to manifest itself not in the clinique alone, but in other parts of the city. Strangely enough, just at the time when the death-rate was so alarming in the hospital, neither in Vienna nor in the neighbourhood was there any aggravation in the condition of those liable to childbed fever. Semmelweis noticed also that the seasons had no influence on the origin or termination of the malady. He noticed, lastly, that when the clinique was closed no fatal cases occurred elsewhere; and experience taught him already that, if deliveries took place outside the walls of the hospital, such patients remained free from fatal attacks. This made it self-evident that the cause of mortality must be looked for in local—that is, in endemic—conditions. But, whilst Semmelweis was perfectly convinced of this, he was unable to accept the explanations which had been brought forward as to such endemicity. It was suggested that *overcrowding* was to blame, but this could not be the cause, since Clinique No. 2, although much smaller, contained by comparison many more patients than Clinique No. 1. Moreover, there was proof that the large number of fever cases was in noway dependent upon the larger or smaller number of admissions. Again, it was alleged that, as the building in which the wards of Clinique No. 1 were situated had served for the accouchement of many thousand patients already, and might therefore be reasonably considered as already contaminated, therefore the greater frequency of fatal cases was to be expected; but the Clinique No. 2 had been made use of in a similar manner, yet its death-rate never rose so high as in the other wards. It was said also that the notoriously bad name of the Clinique No. 1 had so injuriously affected the minds of the patients through fear and anxiety that it also had a great deal to do with the unfavourable result; it was even mentioned that the appearance of the priest walking through the wards to the dying patients had an ominous influence on the rest; still Semmelweis was convinced that none of these surmises could be accepted as a satisfactory explanation. He noticed that such patients in the Clinique No. 1 whose labour lasted from twenty-four to forty-eight hours or longer died almost without an exception, whilst in the other clinique the circumstance of protracted labour in no way produced such an effect. It seemed also very strange that women who were delivered *before* arrival at the hospital—and there were no less than 100 such cases on record—presented a very insignificant death-rate, and so did those who suffered from premature labour. Yet another circumstance seemed inexplicable—namely, that a whole row of patients lying side by side should simultaneously be attacked in Dr. Klein's clinique, whilst no such untoward occurrence had taken place in Clinique No. 2. Semmelweis describes his perplexity in the following words: "The fatal termination of almost all the cases of protracted labour, and the immunity from fever in those who were admitted after delivery, seemed to controvert the theory that the fatality of the Clinique No. 1. was to be attributed to local endemic causes, as was suggested. Again, when I consider the wholesale attacks of patients lying side by side, a circumstance not noticed in the other clinique, where the treatment was in no way more skilful or more conscientious; lastly, the disfavour with which all those were looked upon who were in any way connected with the unfortunate clinique; all these produced a state of mind which rendered my life anything but enviable." Everything seemed uncertain and enigmatical; the suggestions could not appease his doubts; what was positive and self-evident in the matter, meanwhile, was the large number of the dying and of the dead. In his endeavours to minimise the mortality, Semmelweis had recourse to most extraordinary expedients. Dr. Markusovszky watched his proceedings, and narrates how the patients were kept lying on their left side, simply because such was the practice in the other clinique; how he tried to change the details of his treatment, and with what subterfuges he kept away Professor Klein from serious cases, having observed that the Professor's examination was not always conducted with sufficient gentleness and care; how he kept a careful watch over the mortality records of the whole maternity department, in which he was aided by his friend Dr. Lautner, the able assistant to Professor Rokitansky. All this, however, led to no result.

In the midst of these inquiries Semmelweis was called upon to vacate his temporary appointment in favour of

a senior; he therefore prepared for a journey abroad to study the experience of other schools, especially those of Great Britain, the Rotunda of Dublin being one of the first he intended to visit. In March following, the chair he had recently quitted again became vacant, and Semmelweis was appointed to occupy it for two years as assistant professor to Dr. Klein. While scarcely in possession of the chair, the sad intelligence of the death of his friend, Prof. Kolletschka, reached him. The Professor fell a victim to the results of a dissection wound, causing phlebitis, aggravated by pleurisy, pericarditis, peritoneal and cerebral complications, with secondary abscesses. The sad history of the young physician's case made a deep impression on Semmelweis. He says, "Kolletschka's fatal symptoms unveiled to my mind an identity with those I had so often noticed on the deathbed of puerperal cases."[1] The more he thought of Kolletschka's illness, the more he saw reason to conclude that his surmises were correct. The cause of Kolletschka's death, he said, was poisoning by decomposed particles of a dead body; if, therefore, his symptoms were similar to those of the disease which carries off so many women in puerperal condition, then similar causes must exist here as existed in Kolletschka's case. After further research, Semmelweis felt able at last to explain what had seemed so obscure. The prevailing tendency of anatomical studies at Vienna impelled the professors, their assistants, and the students to devote much time to the dissecting-rooms. After dissecting it was customary to wash the soiled hands with soap and water, which was insufficient, as the cadaverous smell emanating from the hands of the dissectors evidently proved that particles of decomposing matter were still adhering to the nails and fingers. These were brought in contact with the genital organs of the parturients during examinations, giving an opportunity for the absorption of septicæmic poison by a process similar to that which happened in Kolletschka's case.

The time had now arrived for Semmelweis to enunciate his doctrine of septicæmic poisoning, and at the same time he pointed out the prophylactic process by the use of antiseptic applications. Starting from this point of view, Semmelweis issued orders in May, 1847, that in the Clinique No. 1 every person, before proceeding to examine any patient, should thoroughly wash his hands with liquid chlorine or chlorinated lime-water. The result of this rule was soon manifest, since in the month of May the percentage of mortality stood at 12·24. By the following November and December the number was reduced to 3·04. In October a very striking incident occurred. A parturient woman suffering from cancer of the uterus was admitted; twelve patients were examined after her; all, except one, suffered from childbed fever, and died. In November eight fatal cases resulted from infection, caused by a patient suffering from caries of the knee giving off offensive emanations which contaminated the air of the ward. Taught by experience based on the above facts, Semmelweis declared that not particles from dead bodies alone, but any material in a state of decomposition proceeding from a living organism, even air contaminated from such sources, may generate symptoms of puerperal fever. Scrupulous attention to the use of disinfectants, combined with separation of patients affected with the disease, brought about the most encouraging results; in the second year of the experiment the death-rate fell to 1·27 per cent., which was even more favourable than the returns of the Clinique No. 2. By the light of his discovery Semmelweis was now in a position to solve all those problems which remained so long unexplained. In the Clinique No. 2 midwives only were employed to attend on patients; they had nothing to do with dissecting and post-mortem examinations; the patients therefore were not exposed to infection from those sources. Again, women who were admitted after their confinement was over were spared the examination, and so were those who suffered from premature labour, being cases not adapted for clinical instruction, and therefore did not share the fate of those who were delivered in the hospital, and during labour frequently examined and exposed to infection. The use of chlorine changed matters entirely. Skoda advised that Semmelweis and Lautner should perform experiments on newly delivered rabbits. The result showed that in these animals symptoms like those in the human subject were produced under exposure to cadaveric infection.

[1] Ætiologie. p. 53.

Semmelweis now thought that the time had arrived when his views should be made generally known. With this object he consulted first his old friends and well-wishers, especially Rokitansky, Skoda, and a few of the rising physicians of Vienna, like Hebra and Helm. The arguments brought forward were quite convincing to all. Skoda declared "that there was not a shadow of a doubt that the truth will carry conviction to everybody's judgment."[2] Communications were made from several quarters to eminent gynæcologists abroad—to men like Dr. Michaelis of Kiel, to Levy of Copenhagen, to Hendrichs of Amsterdam, to Schmidt of Berlin, and to Simpson of Edinburgh. Dr. Arnett read a paper before the Académie de Médécine in Paris; and in England, as mentioned already, Dr. Routh gave a succinct account of his experiences in Vienna. Hebra called the special attention of the profession to the result of Semmelweis's researches in the *Zeitschrift* for December, 1847, and April, 1848, in which mention was made of the approval of the new treatment by Professors Michaelis and Tilanus, who considered the importance of this discovery to be equal to that of Jenner. Hebra was followed by Haller, senior physician and officiating director of the Vienna Hospital, in expounding Semmelweis's theory and experience. He read a paper before the Medical Society of Vienna on Feb. 23rd, 1849, in which he makes the following remarkable observations: "The importance of these experiences for the welfare of the maternity department, and for the hospitals in general, *but particularly for the surgical wards, is beyond calculation, and not merely worthy of consideration by all men of science, but worthy also of special appreciation by the Government*" (the italics are mine.) Haller's words, in alluding to antiseptic surgery, remained unheeded until several decades had passed, and Lister successfully brought into practice what Haller faintly foresaw would some day confer incalculable benefits on humanity.

(To be concluded.)

CASE OF ERYTHEMA NODOSUM OCCURRING WITH SUBACUTE ARTICULAR RHEUMATISM.

BY R. GLASGOW PATTESON, B.A., M.B., B.CH., UNIV. DUB.

THE recent discussion at the Clinical Society as to the connexion between erythema nodosum and rheumatism was one of much interest and suggestiveness. Dr. Stephen Mackenzie, who has carefully investigated the subject, on that occasion adduced a large amount of evidence in favour of the relationship; but in only 17 out of 108 cases examined by him were symptoms of acute or subacute rheumatism present during the attack of erythema; and in only 2 out of these 17 cases did the symptoms of the two diseases appear concurrently. The following case may therefore prove of interest from its evident rarity.

B. M——, a domestic servant, aged nineteen, first noticed pains in her ankles when she awoke on the morning of April 26th. She stated she was quite well on going to bed the previous night, and did not at first pay any attention to the pain, as she thought she had caught cold the week before by substituting a light dress for the heavier one she had been previously wearing. During the day the pains extended up her legs, on the front of which she now noticed some red and painful spots, excessively tender to the touch. The pains increased much in intensity, and the next day the knees became affected as well, so that she was hardly able to get through her work. On the 28th she was quite unfit for work, and when I saw her in the evening her condition was as follows. She complained of pains in the ankles, in the knees (especially the right), and in the wrists, all of which joints were red, swollen, and tender. There was some slight effusion into the right knee-joint. There was no gastric disturbance, no fever, and the pulse was strong and quiet. A well-marked eruption of erythema nodosum was present on both legs. On the front of the left leg about the junction of the upper and middle thirds of the tibia was a raised oval patch, tense and shining, of a vivid redness in

[2] Zeitschrift der K. K. Gesellschaft der Aerzte in Wien. Jahrgang vi., B. i., p. 107.

the central portion and fading away gradually in the surrounding skin. It was about 1½ in. in length by ¾ in. in breadth, and its long axis lay parallel to the tibial crest. A somewhat smaller but exactly similar patch existed on the opposite leg about the middle of the tibial crest; and many smaller but less distinctly oval spots, presenting similar characteristics, were scattered over the anterior surfaces of both legs. They were very tender and painful, and both limbs felt hotter than normal, but there was no general elevation of the body temperature. The patient was a stout healthy girl, had never been previously ill, except when a child with measles, and there was no history, as far as she knew, of rheumatism in her family. She was ordered to stay in bed; the joints were wrapped in wool; and sodium salicylate was given in fifteen-grain doses every third hour.

April 29th.—The patient slept well, and felt better this morning, but still complained of pains shooting about the various larger joints. She was bathed in profuse perspiration, so that she had to be placed between blankets; but there was no fever, the temperature in the axilla being 98·6° F.; pulse 88; the heart sounds normal. No further spots were noticed on the legs, but a few patches of acne pustulosa and of tinea versicolor were observed on the chest. Evening temperature 99·4°; pulse 90.

30th.—The pains have almost ceased, the eruption of erythema is less painful, and the bright redness is fading. The spots have now changed to a dark colour in the centre, with only a marginal zone of redness, but are still distinctly elevated. There was profuse perspiration during the night, but less during the day. The effusion which was present in the right knee-joint has been absorbed. Evening temperature 98·7°; pulse 80.

May 1st.—The smaller patches on the legs have now subsided, and are only visible as slight discolourations under the skin; but the two larger ones on the crests of the tibia are still slightly raised, and have assumed a dark-greenish colour. The swellings of the joints have disappeared, and there is no pain in them either at rest or on movement. The profuse sweating has stopped. The salicylate was restricted to one dose (fifteen grains) night and morning. Heart normal; also the temperature.

May 2nd.—Sat up for a few hours yesterday evening, and feels no bad effects. The spots have now sunk to the level of the surrounding skin, but present a distinct yellowish discolouration. From this date she progressed satisfactorily for some days, but on the 7th a recurrence of the pains, accompanied with a fresh eruption of the erythema, occurred. The pains rapidly subsided under the influence of the salicylate combined with rest, and the spots of erythema gradually disappeared, passing through the same phases as in the first attack. There was no recurrence after this, and, except for slight pains felt in the ankles after any over-exertion, she was practically well. The heart was unaffected throughout both attacks. A short change to the country completed the cure.

As points of interest in the case, we may notice the concurrent appearance of the erythema and the articular rheumatism; the absence of any history of previous rheumatism on the part of the patient, or in her family (if reliable); and the rapid subsidence of the rheumatic symptoms. Whether this latter result is to be attributed to the rest in bed or to the sodium salicylate administered I will not undertake to say.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The Quarterly Court of the above Society was held at 53, Berners-street, on July 14th, at 8 P.M. Dr. Iliff, vice-president, was in the chair. One member was elected, the resignations of two were accepted, four were reported as having ceased to be members, and the deaths of five were announced. Three fresh applications for grants were read from three widows, and assistance at the rate of £25, £35, and £50 per annum was given to them. The deaths of two widows were reported; one had been in receipt of £40 per annum since 1858, the other of £35 per annum since 1864. Grants amounting to £1353 were made to the sixty-two widows, the nine orphans on the books, and the three orphans on the Copeland Fund. The expenses of the quarter were about £37. A legacy of £300 from the late Dr. Harvey Owen was reported by the treasurer.

ST. THOMAS'S HOSPITAL.

TWO CASES OF FRACTURE OF THE BASE OF THE SKULL; RECOVERY.

(Under the care of Sir W. MAC CORMAC.)

IN THE LANCET for Jan. 16th of this year, p. 105, we published notes of a case of fracture of the base of the skull with extensive fracture of the bones of the face, followed by paralysis of the external rectus and optic neuritis. The first of the following two cases may well be read in connexion with that, for in extent of injury received, subsequent development of symptoms, and result, there is great similarity between the two. The case which we now publish, however, was complicated by the presence of a discharge from the ear of old standing, and probably of fetid character, for it was not long before the hæmorrhage from the ear, which ensued on the fracture, gave way to a profuse and very offensive purulent discharge (a similar discharge flowed from the nose), giving cause to fear the onset of septic meningitis or of pyæmia, a fear which was not allayed by the inflammatory swelling of the face and the formation of points of suppuration in or near the fractured facial bones. That basal meningitis ensued would appear from the condition of the eyes, but that it was of septic character is disproved by the temperature record and the result. These, also with the fact that the suppuration was limited to the fractures of the facial bones, and the absence of constitutional symptoms, negative pyæmia. The second case is chiefly remarkable for the very large quantity of cerebro-spinal fluid which flowed from the ear, which commenced soon after the injury and continued for ten days. That it was cerebro-spinal fluid was proved by chemical examination, the large quantity collected making it easy to apply tests. From the account it would appear that the cerebral symptoms were comparatively slight, severe headache being the most marked. It would come under the heading of the first group of cases (as arranged by Hewett), in which watery discharge from the ear occurs, and indicates fracture through the internal auditory meatus. It is usually a grave symptom.

CASE 1. *Fracture of the Base of the Skull, of the Bones of the Face, and Left Ulna; Suppuration at the points of fracture; Optic Neuritis; Recovery.*—G. D——, aged nine, a schoolboy, was admitted into Leopold ward on March 15th, 1885, at 5 P.M., having been knocked down and run over by a carriage and pair about three-quarters of an hour previously. At the same time his companion, who had likewise been run over by the same carriage, was admitted with fractured base, but only lived two hours. When seen, the boy was quite unconscious, bleeding profusely from the right ear and both nostrils. The pupils were contracted, the left being smaller than the right. The eyelids and the surrounding parts were bruised and swollen, and there was hæmorrhage under the left conjunctiva. The right mastoid process was bruised. There was fracture of the nasal bones, of the superior maxillæ with some separation, of the lower jaw in front of the left incisor tooth, the right half being displaced downwards. The left ulna was broken in the middle of the shaft, there being free movement, with crepitus and considerable bruising of the part. The temperature was 95°, and the patient was suffering from shock. He had marked paralysis of the left side of the face. The head was shaved and an ice-bag applied to it. Two grains of calomel were administered. Anterior and posterior splints were applied to the forearm.

March 16th.—The calomel had acted and the patient was better, answering "Yes" and "No" to questions, but was very irritable. Pulse 136; temperature still low (97°). The discharge from both the nose and ears was purulent and very offensive. On inquiry it was found that the boy had

a discharge from the ears before the accident, which had existed since childhood. There has been no vomiting since admission.

17th.—The tissues over the right mastoid process are œdematous. The left eye is almost closed by swelling. Ophthalmoscopic examination of the right fundus showed commencing optic neuritis with retinal hæmorrhages. Pulse 120. Temperature 98°; last night, 95·6°.

18th.—The patient is more irritable. The scalp and forehead are very œdematous, and there is a well-marked depression on the left side of the frontal bone. There is more discharge from the nostrils. Temperature 100·6°.

19th (evening).—The patient is more conscious and complains of headache, is very drowsy, less irritable, and has been quiet during the day. The left eye is closed by œdema, which extends to the left side of the face. The right optic disc is much swollen. The tongue is very dry, the mouth being kept open for respiration, as the nostrils are blocked by the discharge. Bowels acting freely after medicine. Passes urine when induced to do so, otherwise retains it, as much as thirty ounces having been passed at one time. Pulse 104; respiration quiet. Breath very offensive.

21st.—The inflammatory œdema has spread down the left side of the face, which is fixed by it. Is quite sensible, and answers questions when roused; complains of headache, and is drowsy. Pulse 96. Ordered five minims of tincture of opium every six hours.

23rd.—The swelling on the left side of the face is less, and he is able to open the left eye slightly. Left facial paralysis very marked. Tongue very dry. He slept after a small quantity of morphia administered subcutaneously, but was whining occasionally during the night. Pulse 88. There is slight occasional twitching of the right side of the face.

24th.—The facial paralysis is less marked, and there is no twitching of the right side of the face. Pulse 76, quiet and full. Temperature 99° to 99·8°; last night, 100·2°.

26th.—Has continued to improve. The discharge from the nostrils has almost ceased, but that from the right ear is profuse. The inflammatory swelling of the face has much diminished, and the patient opens the left eye. There is fluctuation in the upper eyelid.

28th.—The facial paralysis is still very marked. There is paralysis of the right external rectus muscle with considerable internal squint. The left eye turns inwards when he attempts to look upwards; the right acts normally in that direction. There is now suppuration over the right mastoid process, behind the ear, in the left upper eyelid, and under the symphysis menti on the left side, which does not apparently communicate with the fracture of the lower jaw, there being a free discharge of pus from that into the mouth. Temperature, morning, 98·2°; evening, 98·8°.

April 3rd.—Hammond's splint was applied to the jaw, chloroform being administered for that purpose. There is a hole in the posterior part of the hard palate admitting the finger, and two pieces of necrosed bone were removed from the roof of the mouth.

4th.—The abscesses below the jaw and behind the right ear were incised.

11th.—He is now emaciated and pale; sleeps well, but sometimes cries out in his sleep; an occasional dose of tincture of opium (five minims) is required. He is very deaf on both sides, only hearing a watch on contact. For the last fortnight there has been at intervals an offensive discharge from the left ear. The discharge from the right continues, and also that from the incision over the mastoid process, water passing from one to the other on syringing. An abscess has formed over the left malar bone. The paralysis of the face and eye is still marked. The patient takes food well. Aperients are occasionally required.

17th.—Ophthalmoscopical examination of the eye showed the right disc to be pale, with little if any swelling, but outline indistinct. Vessels only slightly tortuous.

23rd.—The eyes can be moved in any direction, and there is still an internal squint visible.

May 2nd.—Splints removed from the forearm; union good.

5th.—The boy is now able to sit up in bed and feed himself, all the wounds being healed excepting the one over the fractured jaw.

18th.—There is not much change in the facial paralysis. The right eye usually looks upwards and inwards, but both eyes can be moved in any direction. The hole in the hard palate has almost healed. There is still a sinus over the seat of the fracture of the lower jaw.

This sinus closed before the patient left (June 3rd), but the facial paralysis persisted. He was still deaf. He was in the hospital eighty days. The highest temperature during this time was 102° on the evening of April 21st.

CASE 2. *Fracture of the Base of the Skull; Continuous Discharge of Cerebro-spinal Fluid from the Ear for ten days; Recovery.*—B. G——, aged twenty-five, a carpenter, was admitted into the Leopold ward, under the care of Sir W. Mac Cormac, on July 2nd, 1885. A short time before admission a plank fell on the back of his head, knocking him down and rendering him insensible for ten minutes. He bled from the right ear profusely. When examined he was found to have a red mark on the back of the head where he had been struck. His pupils were equal and acting to light. He was quite conscious, complaining only of headache and vomiting (which was severe), lasting until the following morning, when it ceased. There was a profuse discharge of watery fluid tinged with blood flowing from the right ear; temperature 95·8°. His head was shaved, an ice-bag applied to the head, and a smart purgative administered.

July 3rd.—Retention of urine; the urine drawn off twice a day with the catheter, any straining causing the discharge from the ear to flow more freely. Bowels acting. Temperature, morning, 98·8°; evening, 101·8°.

4th.—Complains of a splitting headache. Tongue furred and white. The temperature rose from 101·4° @ 2 A.M. to 104° at 8 P.M.

6th.—The discharge from the ear is very profuse, saturating the pillow. During the course of two hours and a half, no less than one pint and a half of fluid, having a greenish tinge and the reactions of cerebro-spinal fluid, flowed from the right ear.

7th.—The headache, which is chiefly occipital, is now comparatively slight. He is much improved and quite intelligent. Pupils equal and acting to light. The fluid is not flowing so freely; it is still clear. He only hears a watch on contact. There is slight extravasation over the right mastoid process. Tongue furred and white. Bowels acting after medicine.

10th.—Headache less. He can sleep without a chloral draught, which has been required on other nights. Pulse 72.

12th.—The discharge from the ear ceased in the afternoon. The temperature, which had been 100° at noon, rose to 103° in the evening; it has usually reached 103° or passed this point in the evening.

13th.—The eyes were examined with the ophthalmoscope. There was no optic neuritis, but a peculiar rosy appearance of the fundus, without evident dilatation of vessels.

15th.—He was not so well after the discharge ceased, there being much headache and pain in the back of the neck and flushing of the face. The headache was very severe, making him cry out with the pain. He became delirious and noisy. Pupils continued equal, and acted to light. Last night and this morning he has been better, having very slight pain excepting on sudden movement, which immediately brings it on.

18th.—There is now no pain or headache, but only slight and momentary giddiness if the patient bends forward. He is otherwise quite well.

24th.—There is now very slight giddiness on bending forward.

On the 14th the lowest temperature recorded since admission (99°) was registered; on the 15th it reached 101°, and on the 16th 100°. After this it did not again exceed 99° on the 18th, becoming normal on the 19th, and continuing so. The man was in the hospital fifty-five days.

MELBOURNE HOSPITAL, AUSTRALIA.

CASE OF SIMULTANEOUS AMPUTATION OF THE RIGHT THIGH AND DISARTICULATION OF THE LEFT KNEE FOR RAILWAY INJURY; RECOVERY.

(Under the care of Mr. R. A. STIRLING.)

THIS case is put on record as an instance of singular tenacity of life under injuries which usually prove rapidly fatal.

John S——, aged nineteen, was admitted at midnight on Dec. 18th, 1885. An hour previously, while engaged shunting on the Government railways, which are situated a mile from the hospital, he had fallen on the rails, was struck by the buffers of a carriage in motion, and sustained, through the wheels passing over him, a compound comminuted

fracture of the lower part of the right thigh and the upper part of the left leg, with extensive laceration of the soft parts. Hæmorrhage had been profuse, and on admission he was suffering much from shock, but was sensible and could speak in a whisper.

The patient, a strong-looking, very muscular lad, was given a few whiffs of the A.C.E. mixture, and in this incompletely anæsthetic state the right thigh was amputated in the usual way at the junction of the middle and lower thirds, with skin flaps and circular muscles. During this operation the pulse flagged much, although not more than a few drops of blood were lost. Enemata of peptonised beef-tea and brandy, with hypodermic injections of ether, were given. While an assistant was dressing the stump disarticulation at the left knee-joint was performed, the injury being confined to the leg, and the soft parts, though in a doubtful state as regards bruising, still warranting the hope of vitality. Mr. Pollock's method by the long anterior flap was most suitable. The patella and cartilages were retained. The second procedure added little to the shock, and little blood was lost. All the large vessels were tied with kangaroo tendon prepared after Mr. Girdlestone's plan. Antiseptic precautions and dressings were used for the first but not for the second operation, as to save time I dressed the knee-stump with carbolic oil and opium dressing. In an hour and five minutes from admission the patient was in bed in the ward.

At 10 A.M. the next morning his temperature was normal and pulse 120. He suffered from persistent vomiting for several days, retaining nothing but a little thick gruel, and being fed by enemata. The progress towards convalescence was retarded by the buffer injuries of the left side, including fracture of the sixth and seventh ribs and emphysema. There was no tendency of any of the flaps to slough, and the left stump healed quicker than the right. He was discharged on Feb. 15th, 1886, with soundly healed stumps, and when last seen was growing very stout.

Medical Societies.

SOCIETY OF MEDICAL MEN QUALIFIED IN SANITARY SCIENCE.

THE inaugural and first annual meeting of the Society was held at the Holborn Restaurant on July 22nd, the President, Sir Joseph Fayrer, K.C.S.I., being in the chair. Before the Council's Annual Report was read and other business had been done the President delivered the following address:—

"Gentlemen,—I have to congratulate you, on this the first annual meeting of the Society of Medical Men qualified in Sanitary Science, on the success which has already attended the efforts you have made towards the foundation of a Society which promises, on the one hand, to be productive of great benefit to the profession by ensuring the due recognition of your rights and privileges, and to the public, on the other, by guaranteeing the diffusion of sanitary knowledge, and the practical application of the laws which govern the protection of health, the preservation from disease, and indicate the most efficient means of dealing with it should it arise. It is an assertion of your rights and duties as medical men not merely to treat disease, but to deal with all that tends to prevent it, as well as to preserve health. This obviously paramount duty of medical men has too long been lost sight of, but the time has come when it may no longer be ignored, and it is but right that in civil life—as already, indeed, happens in the public services—sanitary science, as applied to the preservation of public health, should be under medical guidance and control. The ninety-five medical men who have already specially qualified themselves for these duties, and who form the nucleus of this Society, are, we may hope, the pioneers of a movement which will ultimately receive great extension and include all medical men in the scope of its operations, and gradually but surely vindicate the principle that the prevention of disease and the preservation of health are an integral part of the duties of the physician, as is the treatment of disease. Your Society, which took its rise so recently as April of the [illegible] year, has already made most satisfactory progress, [illegible] on its [illegible] nearly half of the medical men [illegible] qualification in sanitary science from the various bodies entitled to grant these diplomas, and twelve honorary members eminently distinguished in sanitary science. We trust, and there is a good reason for expressing a confident hope that it will be so, that many others will join the Society, and that its prosperity and utility will be thereby thoroughly established and confirmed. It appears that of the whole body of the medical profession, 200 only are now qualified in sanitary science, and of these 175 are in the United Kingdom. Let us hope that the numbers will rapidly increase. Of the 95 members of the Society, there are in London 35; provinces, 46; Scotland, 7; Ireland, 6; and in Australia, 1. Of these, the University of Cambridge supplies 60 per cent.; University of Edinburgh, 12 per cent.; University of Dublin, 7 per cent.; University of London, 5 per cent.; Royal College of Physicians, Edinburgh, 5 per cent.; King and Queen's College of Physicians, Ireland, 4 per cent.; Royal College of Physicians, London, 3 per cent.; University of Glasgow, 2 per cent.; University of Oxford, 1 per cent.; and University of Durham, 1 per cent. The objects proposed and set forth in the preamble of your rules are such as must commend themselves to all. I am much pleased to congratulate you on having attained the first object—registration of sanitary science qualifications, as seen by Section 21 of the Medical Act, 1886, just passed. The second of the objects named will naturally follow as a result. These, as the others, have to be worked out in the future, and I think I see in the energy and tact which have carried out the scheme so far and so satisfactorily evidence and assurance that the two latter clauses will continue to be the aim and object of the Society, raising it to so much importance that its influence for good will spread far and wide. It appears to me that the organisation of the Society is well devised, and bears evidence of much careful thought and knowledge of the objects aimed at. The rules are simple, practical, and calculated to carry on the work without friction or confusion. The general management is entrusted to a Council well selected, which has already held seven meetings, and is subject to such changes and variations in its *personnel*, as experience has shown conduces generally to the efficient working of a governing body. I cannot refrain from observing that the Society is especially indebted to certain of its members for the progress it has made, and for the practical business-like character it has assumed. It would be an unpardonable omission were I to neglect to say how truly we all recognise and cordially acknowledge the untiring and well-directed energies of our indefatigable honorary secretary, Mr. Cooney; of our chairman of Council, Dr. W. R. Smith; of Dr. Joseph Smith, Dr. Sykes, and others whose efforts in and out of the Council have done so much for the Society. We can only, in thanking them, say that we trust their energetic efforts will be unremitting and their interest unabated in the Society, which already owes them so much. In conclusion, I have only to add that I return you my best thanks for the honour you have done me in electing me to be your President, and to assure you that it will always be a great pleasure to me to do anything in my power to forward the interests of the Society."

Letters of apology and inability to attend were received from Sir Douglas Maclagan, Sir Charles Cameron, Professor Gairdner, Drs. Thorne Thorne, Barry, Hinckes Bird, Campbell Munro, and others.

After the annual meeting, the members and their friends dined together at the Holborn Restaurant, in celebration of the inauguration of the Society, and in honour of its primary object being so speedily obtained—viz., the State recognition of public health qualifications in the new Medical Bill.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on June 4th, J. B. Bradbury, M.D., President, in the chair, the following communications were made:—

The Medical and Surgical Treatment of Fibro-myoma Uteri.—Mr. J. KNOWSLEY THORNTON (London) commenced with some remarks on the general medical and dietetic treatment of patients suffering from uterine fibro-myoma; objecting to the use of stimulants and iron, and urging the value of ergot employed between the periods, and the reasons against its use during the flow. Surgical aid could often be avoided by judicious diet, medicine, and mode of life. He then proceeded to give in detail three cases upon which he

had recently operated, to illustrate the difficulties in differential diagnosis between solid ovarian tumours and fibro-myomata, and between cystic ovarian tumours and fibro-cysts of the uterus, using the tumours (which he had on the table) to demonstrate the various points as he discussed the cases. His conclusions were: 1. That some ovarian cysts, from their method of growth and the way in which they stretch out the layers of the broad ligament, uterus, and bladder, cannot be differentiated from uterine tumours. 2. That some uterine fibro-cysts, especially if complicated by solid fibro-myomata, cannot be differentiated from ovarian cysts. 3. That some pedunculate fibro-myomata grow so fast, cause such emaciation and so little hæmorrhage, that they cannot be differentiated from solid ovarian sarcomata. 4. That the ovarian cysts, which burrow deeply in the cellular tissue round the uterus, are slow and uncertain in their growth, are often causes of considerable pain and distress, are apt to give rise to inflammatory action, which, if allowed to recur from time to time, renders their removal extremely difficult, and, from their seat, are especially liable to interfere with the action of the kidneys and lead to serious inflammatory or cystic changes in these organs. 5. That in view of the impossibility of exact diagnosis in some cases, exploratory operation should be advised whenever there is danger of interference with the ureters by intra-pelvic pressure, whenever the presence of the tumour gives rise to recurrent attacks of pelvic inflammation, and whenever other symptoms indicate operation. 6. That the operator who undertakes to perform ovariotomy must be prepared to find himself face to face with the most formidable hysterectomy which it is possible to perform, and therefore no one should undertake these operations without being fully provided with the appliances necessary for the completion of such exceptional cases. In his concluding remarks, he dwelt upon the impossibility, when operating for fibro-myoma, of deciding beforehand whether the case was suitable for hysterectomy or for the removal of the uterine appendages, and then referred to some practical points in the performance of these operations. He had operated eighty-eight times for uterine fibro-myoma, and seventy-four of the patients were alive and well, eleven of the deaths having occurred in the first half of the cases and only three in the second half.

Operation on Movable Kidney.—Mr. FRANCIS read the notes of a case of movable kidney, associated with pyonephrosis, which was under the care of Professor Humphry in Addenbrooke's Hospital. The left kidney was about twice the natural size, and could be easily felt from the front of the abdomen, and moved slightly upwards and downwards and considerably from before backwards; it impinged against the abdominal wall in the erect position, forming a slight eminence; a considerable amount of pus was passed in the urine; the mobility of the kidney caused no discomfort at all and the general condition of the patient was very good. The patient was a tailoress, aged twenty-six, leading a sedentary life. The abdominal walls were firm and natural; and there was no history of the recognised predisposing causes of movable kidney. The condition of the uterus was not ascertained, but there were no uterine symptoms. For many years she had had cutting pains in the urethra during micturition, and occasional pains in the lumbar regions, especially on the left side. Five years before she had passed a small stone; lately she had passed a few clots of blood, and for a month previously there had been pus in the urine. The movable kidney she had noticed for a fortnight. On March 30th, 1886, an exploration was performed in the loin by the usual nephrotomy incision, and the kidney forced backwards into the wound with some difficulty, owing to its extreme mobility; the pelvis of the ureter was found much enlarged, and was incised in two places and a large amount of pus escaped; no stone was felt in the calices, nor on probing the kidney with a needle. A bent tube was passed through the incisions into the pelvis of the ureter, which served to moor the kidney and drain the pelvis. The perinephric fat was natural in amount and consistency, and the peritoneum was not seen during the operation. The wound healed completely in a few weeks, leaving no fistula; the mobility of the kidney was much lessened, but there was no diminution in the amount of pus in the urine.

THE wife of a labourer of Milton, near Northampton, recently gave birth to four children. Three were still-born, and the other survived only a few hours. The mother also expired the same day.

Reviews and Notices of Books.

On Diseases of the Lungs and Pleuræ, including Consumption. By R. DOUGLAS POWELL, M.D. Lond. Third Edition. London: H. K. Lewis. 1886.

IN few departments is our medical literature so rich as in that of pulmonary disease, reflecting therein the preponderating prevalence of such affections amongst the dwellers in our variable British climate. The classical treatises of Williams and of Walshe, of Fuller and of Bennett, are amongst the fruits of the study to which these diseases have been subjected; and in welcoming the present work, which the author has considerably revised and extended, we think that it deserves to rank beside those of well-established fame. It is no demerit that the author abstains to a large extent from overburdening the text with speculative opinions and elaborate analyses. This method of dealing with disease may well be left for the most part to the erudition of the Continental professors. Dr. Powell has chosen the more practically valuable path of personal experience, and his book is in consequence all the more useful and readable. It opens with a chapter upon the anatomy and functions of the lungs, in the course of which we find fully discussed the important part played in the respiratory mechanism by the elasticity of the chest walls, a subject which had received but scant attention until Dr. Powell himself made his observations upon it. Another chapter is devoted to the physical examination of the chest, comprising a lucid exposition of the *rationale* of physical signs, aided by a useful table of definitions and synonyms. We note, in passing, that a twofold origin is ascribed to the vesicular murmur—namely, a glottic bruit and a number of minor bruits produced at the openings of the pulmonary alveoli; whilst all other breath-sounds are referred to modifications of the bruit produced at the glottis. The chapters devoted to pleurisy, pneumonia, and phthisis are especially noticeable for the precision and care with which the facts are presented, and the clearness with which the views are expressed. The subject of asthma, complicated and difficult as it is, especially in regard to its etiology, is one which Dr. Powell treats in a systematic manner, and his remarks upon the treatment of this affection are evidently based upon a wide experience. Bronchitis, emphysema, pneumothorax, contraction and dilatation of bronchi, pulmonary abscess and gangrene, hæmoptysis, hydatid of the lung, and other topics, all receive separate consideration.

The limits of this notice will not allow us to do more than glance at the salient features of a few of these chapters. For instance, in dealing with pleural effusion, the author is very successful in showing what signs are essential and what non-essential to a correct diagnosis, and we know of no work of this class where these distinctions are so succinctly and plainly described. Upon the treatment of pleural effusion and empyema Dr. Powell is as methodical and explicit in directions as any surgeon could be, and it is plain that all he writes is the outcome of his own experience. Indeed, the intrusion of surgery into thoracic disease is further illustrated in another chapter, which is devoted to the surgical treatment of pulmonary cavities. We may commend Dr. Powell's remarks on this head, especially on the difficulties of discriminating pleural from pulmonary cavities, and the inutility of attempting to drain tubercular vomicæ, to those who would too ardently advocate an undiscriminating interference. That much remains to be done in this direction few will be disposed to deny; but hitherto the records are too scanty to show how far it is advisable to go. Upon the subject of pneumonia, the author evidently concurs in the doctrine that it is a specific disease—like rheumatism and erysipelas; but at the same time he hesitates to admit that the

pneumococcus is anything more than an epiphyte. Attention is drawn, however, to the records of cases of infectious and contagious pneumonia, and the inference is gathered that there are several types or forms of the acute disease. We note that he approves of the application of cold (packing or bathing) in cases of pneumonia where the pyrexia is high, and his advice respecting the treatment during resolution is judicious and timely. The subject of phthisis, as may naturally be expected, is dealt with in considerable detail. The pathological factors in the disease are distinguished as (1) inflammatory, (2) tubercle, (3) impaired respiratory movement, and (4) bacterial organisms; and although the constant concomitance of the bacillus is recognised, it is clear from the position taken by Dr. Powell that he is somewhat sceptical as to its holding the very definite etiological relation to phthisis that has been assigned to it. But the description of the forms of the disease which is given by the author is based as much upon clinical facts as upon the ultimate pathological states; and herein he has rendered a good service by reminding us that the course taken by phthisis is by no means uniform and harmonious, but most chequered and disorderly. The value of prophylaxis, and especially of climatic treatment, is strongly insisted on; and, indeed, there is throughout all the advice given a tone of "sweet reasonableness" coupled with hopefulness, calculated to aid the practitioner in taking less gloomy views upon the outlook of the cases he has to treat. In fine, then, we commend this book as one which should be in the hands of every practitioner. It is plainly the outcome of wide experience, and it has been written in a thoughtful and practical manner, so that no one who studies its pages can fail to derive therefrom much that will stand him in good stead at the bedside.

The First Appendix to the Medical Digest, including the years 1882-85 and early part of 1886. By RICHARD NEALE, M.D. Lond. London: Ledger, Smith, and Co. 1886.

EVERY medical man who has an aspiration beyond mere rule-of-thumb practice, and every student of medical literature, will welcome the publication of the first appendix to Dr. Neale's valuable "Medical Digest." The work, it will be remembered, first appeared in the year 1877, under the auspices of the New Sydenham Society. The second edition, considerably enlarged, was published in the year 1882; and now, after an interval of four years, an appendix is issued, consisting of nearly two hundred and fifty pages of printed matter, and containing several thousand additional references. The entire work comprises a tolerably complete, classified reference-index to the principal English medical periodicals for the last forty years. Originally undertaken for the author's individual benefit, and without any thought of future publication, it has by slow degrees grown into an important work of reference, almost indispensable to every intelligent practitioner and every earnest student of medicine. In the hands of such it will be found to supply a ready means of information regarding all the more important discoveries, doctrines, and modes of treatment in the various departments of medicine during the time which it covers. The book contains considerably over 12,000 separate references, and probably more than ten times as many distinct entries. It supplies at once an index to medical literature for the last forty years, and a summary of its results. It is chiefly with reference to the latter characteristic that the author has selected the title "Medical Digest." There were doubtless many who from the first recognised the great value of Dr. Neale's labours; but there is reason to think that the significance and importance of these labours have not yet been so fully appreciated as they deserve.

In spite of the great amount of thought, time, and money necessarily expended in preparing and printing such a work, it will be seen that everything has been done to make the "Digest" reasonably accessible to most medical men. The undertaking is so useful and so commendable that we would fain hope there need be no risk of its discontinuance from lack of sufficient and suitable support.

Die Rhabditiden und ihre Medicinische Bedeutung. Von Dr. L. OERLEY. Berlin: 1886.

DR. LADISLAUS OERLEY of Buda-Pesth, who is well known as a student of nematoid worms, has published an interesting and important monograph on the Rhabditidæ. This group of ordinarily free-living worms has attracted considerable attention from the belief that they were the cause of the fever epidemic on board the school-ship *Cornwall* in the autumn of 1879. One of the boys attacked by the fever died, and after two months his body, as our readers will remember, was exhumed and dissected. In the muscles of the body Dr. Power recognised the presence of a round worm which he called a trichina; later, Professor Bastian applied to the organism the name of Pelodera setigera: and the late Dr. T. Spencer Cobbold called it Rhabditis cornwalli. On his visit to this country in 1881, Dr. Oerley visited the place of burial, and obtained from the ground a number of examples of a free-living round worm; this he recognised to be the Rhabditis terricola described by Dujardin in 1845; and the English helminthologists were convinced by him that they had given new names to an already named form. With regard to the life history of Rhabditidæ, Dr. Oerley is able to show that they cannot live in the intestines of mammals; or, in other words, they may be eaten with impunity by man. This being so, it is clear that the Rhabditis was not the cause of the *Cornwall* epidemic. Rhabditis, in fact, like Anguillula, is a form which always lives a free life, and it might therefore, as it is now by Dr. Oerley, be separated from those rhabditiform genera—Angiostomum and Rhabdonema—in which one stage is parasitic and hermaphrodite, and the other free and dicœcious. Of these latter or heterogeneous forms, the most interesting to the physician is Rhabdonema strongyloides, for it is the cause of Cochin-China diarrhœa, although, indeed, it is not, unfortunately, confined to that or even to tropical countries, having been found in Italy, Switzerland, and Hungary. Dr. Oerley gives an account of what is known as to this form, and makes corrections of various previously received opinions. The physician who desires to make himself acquainted with the bibliography, the method of investigation, the principles of classification, the specific characters, or the life histories of these little known and obscure worms, will find Dr. Oerley's work a useful and indeed necessary assistance in his labours.

THE LATE DR. MOXON.

To the Editor of THE LANCET.

SIR,—I shall be obliged by your affording me space for a few lines expressive of my deep sorrow and regret at learning of the sudden death of Dr. Moxon. As I have left London earlier than usual I am without particulars of this sad occurrence. Guy's has indeed been very unfortunate in the loss of two men so distinguished and so well fitted to advance her interests as Dr. Fagge and Dr. Moxon, and both cut down in the noontide of a growing and deserved fame. Dr. Moxon had carefully cultivated his finely discriminating intellect, and his writings evince exact observation and the keenest perception. When his reasonings and conclusions did not compel assent, they never failed to arouse and quicken attention, and to throw light upon the question at issue. His death will call forth a wide expression of the deepest sympathy.

I am, Sir, your obedient servant,

Cresswell Hall, Morpeth, July 26th, 1886. WILLIAM W. GULL.

THE LANCET.

LONDON: SATURDAY, JULY 31, 1886.

CERTAIN reports prepared by Her Majesty's consuls in different foreign countries are periodically selected for publication by the Foreign Office in an official volume, and some of those recently issued have a medical interest, because they give some account of the cholera in various portions of Southern Europe during the past year. Commencing with France, we find that at Marseilles the epidemics of 1884 and 1885 brought about a state of almost unexampled commercial depression. But the consul is of opinion that Marseilles has itself very much to blame for its recurring epidemics by neglecting sanitary precautions. When disease is prevalent there, promises of improvement seem to abound, and when the scare is over nothing is done. The drainage system he describes as very bad, the main sewers opening into the docks where the vessels lie, and bringing about a state of offensiveness and nuisance which no person who has not had the misfortune of experiencing it can form any idea of, especially during the nights in summer. The landing of invalids and time-expired men from Tonquin, where cholera has prevailed, has been a constant additional source of alarm, and it is to be hoped that certain special arrangements with a view to secure disembarkation without danger to the city, which were promised some time back, will be carried out in earnest. The present year is stated to have commenced badly for Marseilles, small-pox, lung disease, and typhoid fever being prevalent.

From Spain there are several interesting consular reports. In Barcelona, it is stated, depression of trade and industry was most marked. Anything like stability was upset on the recurrence of cholera in 1885, when the paralysation was so great that all business came to a standstill, owing to the flight of the wealthy families and the consequent closing of the factories and the dismissal of the factory hands. In this way the retail traders were deprived of their usual custom, and the entire population suffered. Curiously enough, however, there was some improvement later on, owing to the inroad of families from Valencia and Murcia, where the disease was still more rife. Added to these evils, thousands of vine plants were destroyed by frost in the beginning of the year, and floods and phylloxera still further contributed to disaster. In all, 1318 fatal attacks of cholera took place in Barcelona during 1885.

The report from the vice-consul at Seville gives an account of one of those eccentricities of administration in connexion with quarantine which, in the eyes of all unprejudiced persons, must go to show how vexatious that useless proceeding can be made. Seville was apparently free from cholera, but, as is well known, it lies inland up the river Guadalquivir. All vessels going up to Seville are compelled to call at San Lucar, a port town at the mouth of the river, and situated in the province of Cadiz, where cholera was prevalent. The result was that vessels from England and other non-infected countries were compelled to present their "manifests" at the port of an infected province, and having done so they were at once regarded as suspect, and not allowed to enter Seville without being detained for "observation" in the river. Innumerable protests, it is stated, were made against this arbitrary detention, but all to no purpose. This result can easily be understood if account be taken of the feelings of the population as shown by their attitude in connexion with land quarantine. All passengers, it appears, arriving even from the neighbouring villages, had to undergo a farce of fumigation, and those coming from or passing into any infected province had to submit to five days' quarantine in a lazaretto fitted up in a ruined convent outside Seville, and destitute of everything but the bare necessaries of life. According to the vice-consul, the Home Secretary sent several orders from Madrid to do away with this illegal lazaretto, and changed the civil governor twice each new one being sent with orders to enforce the stoppage of the unlawful quarantine, and each having to resign on account of the determined attitude of opposition displayed by the population. Finally, the municipality resigned in a body, and the populace one night went to the extent of stoning the governor's official residence. So matters remained until the middle of October, when the epidemic was at an end.

The consul for the district of Malaga also, judging from his experience during the past year, raises a protest against the existing quarantine system. He trusts that, as the result of the late epidemic, the Spaniards may come to learn the uselessness of their measures in this respect, and may be induced to treat foreign shipping in a more liberal and practical manner in the future. The result of their lazarettos and cordons must, it is hoped, have shown them that such precautions are quite unworthy of the faith that was so generally placed in them. Indeed, it is explained how they were worse than useless, whilst the loss and expense inflicted on shipping were incalculable. In short, the references to cholera in the volume under consideration show how the disease was associated with grave sanitary default, and how futile were the efforts to stay its progress in so far as these were limited to restrictions of a quarantine character. England may, in view of this renewed experience, rest satisfied in the assurance that with the organised system of inspection along her coast line, coupled with a steadily progressing improvement in the general sanitary state of the whole community, she is far more secure against the spread of cholera than those amongst her neighbours who prefer to neglect sanitation, and then hurry to spend their money on the useless and utterly unremunerative processes of cordons and lazaretto detentions.

BEYOND question many of our needs are factitious. We have created not a few of the demands it is most difficult to supply, just as we have actively, though not perhaps intentionally, undertaken many of the obligations we find it irksome to discharge. At first sight it may appear that the need for a respite from habitual labour and temporary change of surroundings which recurs to most of us every year is of this nature. There are, however, grounds for believing that this is not the truth, but that wholly independent of custom and even of civilisation, a change in the

mode and place of living for a brief space about once each year is indicated by nature. PLUTARCH mentions the habit of going to the sea for a few weeks annually as prevalent among nearly all communities having access to the coast, even though their migration were a somewhat formidable one. In short, it would seem that change is one of the expediencies, if not the necessities, of healthy living; and no doubt the demand for fresh air has been greatly increased by the formation of populous districts wherein the conditions of life are rendered less natural than rude health requires. Probably the need will increase as time goes on, and those are happy who are able, and sufficiently intelligent, to make the annual holiday as great a relief from the fetters of habit, and as much a stimulus to recuperative nutrition, as it ought to be.

Where to go is *the* question of the hour. We have no intention of anticipating, or even suggesting, the answer. The point raised is a more important one than it is generally considered, and the issue is one that ought to be determined seriously, and as far as possible on purely personal grounds, in each individual case. The first condition of success in the use of change as a relief and restorative is to make the particular change effected not merely complete, but physiological in its adaptation to the special needs of the organism. This is too much left to chance, and, except as regards the movements of avowed invalids, the trusted adviser on matters of health is too seldom consulted. We are strongly of opinion that if the greatest benefit is to be secured, the practitioner ought always to be asked to give advice on the subject, and that, being asked, it should be his aim to search out the particular needs and capabilities of the nerves, blood, muscles, and the organic system generally, and to adjust the remedy of change to the requirements of the person before him not less carefully than he would select the ingredients, determine the proportions, and compose the totality of a prescription for drugs. There is far too much recklessness in this matter. The general notion that change is good prevails, and the manner in which the life is to be varied and the surroundings changed is treated with indifference, even when some small care may be bestowed on the locality and climate.

There are great and grave risks in all travelling. Setting aside the chances of accident, there are the haste and toil of the journey, the peril of exposure to cold by damp beds at hotels and in lodgings (a *very* common cause of illness—far more common than is generally supposed), the danger of infection by contact with the sick or convalescent, of blood-poisoning by impure or contaminated water, of indigestible, or otherwise bad, food. These risks to health ought not to be under-estimated. Many a weakly or susceptible person, going from home jaded, is seriously injured by the contingencies of travel, particularly on the Continent. Speaking generally, we incline to say that it is safer and better for English folk to travel in this country than abroad. Of course, the change is more complete when the surroundings are entirely different, and there is much to be said in favour of a trip to "foreign parts" if there be sufficient vital power to resist and overcome the antagonism of perils by sea and land; but it is always safer, when practicable, to go away for a week's rest and recuperation to some known and trusted place of sojourn before crossing to the Continent, than to rush directly into the midst of dangers when the organism is exhausted and depressed by the monotony of life and work at home. The delay suggested will be more than compensated by the increased preparedness to undertake and enjoy travel after a week of rest and fresh air in the home country.

A common mistake into which tourists fall is the notion that notwithstanding they may be unaccustomed to great muscular activity at home, they must needs be fit for severe exercise in walking, and even climbing mountains, as soon as they go from home, even though they are at that very time specially exhausted. How many failures to derive benefit, and even break-downs and deaths, are due to this blunder! Travelling is fatiguing to all, and particularly to those who are unaccustomed to it; and yet in the quest for health many otherwise sensible persons are induced to encounter the exhausting effects of long and toilsome journeys, often to their serious detriment. A pedestrian or mountain-climber needs careful training for his task if he has not been in training for some months; and even long travelling by railroad calls for some preliminary exercise of a moderate kind to lead up to the continuous toil.

Our immediate purpose will be answered if these few general remarks should have the effect of directing attention to the subject of change, and if they induce those who seek the benefits it is believed to be capable of affording, and those who advise on the subject, to give the questions involved fuller and more detailed consideration. It is not only disappointing, but humiliating, to find disease, or even death, when laboriously seeking for health, and yet that is the untoward experience of too many who are more energetic than wise in the way they utilise the annual holiday season.

THE progress made in the study of Bacteriology is one of the most remarkable facts of modern science. By far the greatest part of our knowledge respecting the nature of these protophytic organisms has been gained within the past decade, and even a shorter span of years embraces the period during which most of the microbes of disease have been discovered and investigated. Every year brings with it a fresh addition to the sum of knowledge upon the subject and already so much has been gained that the diffusion of such knowledge is taking place far beyond the limits of the laboratory and the physician's study. As an instance of this may be cited the extremely interesting volume which forms the latest addition to the series of International Scientific handbooks[1]—a series that contains so much that is useful and that has a real educational value. M. TROUESSART'S work on Microbes, Ferments, and Moulds will do much to enlighten the reading public upon matters which not very long ago were considered as the somewhat precarious property of a few scientific enthusiasts. Bacteriology has a firmer footing now; and the publication of such a work as the recently issued collection of memoirs by KOCH and colleagues by the New Sydenham Society has brough this within the reach of the English student many of the most important inquiries that have gone to strengthen the position and establish the value of this line of research. In this country, also, we have an increasing band of workers, who are adding important facts, and confirming

[1] Published by Messrs. Kegan Paul and Co.

statements already elsewhere made, and thus aiding in the sure but certain work of discovery of the nature of specific disease. The methods of research are comparatively simple, but from the very nature of the subject they require the exercise of the greatest skill and patience. It is not possible for everyone to be a bacteriologist. Life is too short to allow of the pursuit of such a subject to be carried on by those who are busied with the concerns of active professional work. Everything, therefore, which enables the bacteriologist to spread the knowledge of the facts he studies is of advantage, for it enables those who cannot, by force of circumstances pursue this study in practice to at least comprehend the facts and their bearings in relation to disease. The application of photography is one of these methods, and its development in respect to microscopical work is in fair way to be much advanced. Hitherto photomicrography has hardly come up to expectation. Theoretically its advantage over the pen and pencil sketch even when aided by the camera lucida should be great. To have a permanent reproduction of a microscopical specimen faithfully rendered, without any intervention of the microscopist's own interpretation, should be a great gain; but the photographs have mostly been lacking in the sharpness of outline and clearness of detail which the specimen itself presents to the eye. Prof. KOCH has long employed photography to render visible to others the forms of bacteria that are to be discovered in disease. We have now in this country the same work being undertaken, with every advantage of new processes, by such competent hands as those of Mr. CROOKSHANK and Dr. H. GIBBES. Mr. CROOKSHANK'S large collection of photomicrographs has been exhibited at the Royal Society, the Microscopical and Pathological Societies, and on many other occasions, and has called forth well-deserved encomiums. They form at present part of the Photographic Exhibition at Glasgow, and Mr. CROOKSHANK claims for them that they are taken from specimens irrespective of the staining reagent and mounting medium employed; and they are mostly taken with high powers, such as 1-25th in. objective, and even higher. Permanent autotypes, printed in various colours, facilitate the reproduction of the actual appearance of the specimens, and by enlarging from the original negatives a very considerable degree of magnification is attained. Both Mr. CROOKSHANK and Dr. GIBBES deserve credit for showing what may be done by photography, and their work suggests a very useful extension of the process in anatomical and pathological investigations.

WE have received a copy of the regulations drawn up by Dr. C. HAIG-BROWN, and approved by the head master, for the management of the sick of the school, and especially for the steps to be taken in cases of infectious disease. They appear to have been very carefully prepared, and fully justify the opinion we have expressed of the advantage which would arise from having such a code prepared for each school by the medical officer in charge. It also reveals to us the fact that on the present occasion some, at least, of the masters have acted in disregard of the instructions issued under the authority of the head master. The first regulation provides that "if during term time a boy fall ill with an infectious disorder, he must be immediately removed from the house in which he boards, to the sanatorium, in the school ambulance-cab." In the list of diseases requiring isolation, attached to the rules, diphtheria is included. How, then, did it happen that the two cases which occurred in the house where young CARRITT was boarded were not at once removed? We were informed by Dr. BRISTOWE, in his letter to *The Times*, that the retention in the boarding-house was in opposition to the wishes of the medical officer. With whom, then, does the responsibility lie? With the head master or the house master, or with both? Such an occurrence bears strongly in favour of our view that the medical officer of a school should not only have the power to appeal, but be bound to bring to the notice of the governing body any such disregard of sanitary regulations which had been submitted to and approved by it. We give elsewhere a copy of the resolutions passed at a special meeting of the Council of the Medical Officers of Schools Association. We cannot say that we think them in all respects judicious. It appears to us that if carried out they would invest the medical officer with an amount of power which, unless exercised with great judgment, would prove injurious, and might introduce a considerable amount of discord into the school. Dr. C. HAIG-BROWN'S regulations, on the contrary, seem well suited to the purpose, and to provide for almost every contingency, if only there were adequate means in existence for enforcing them when necessary.

Annotations.

"Ne quid nimis."

THE CHOLERA EPIDEMIC IN SOUTHERN EUROPE.

IT is not easy correctly to interpret the significance, as regards the future, of the cholera intelligence received for the week ending July 27th. In so far as Austria is concerned, the positive news is still limited to Trieste and Fiume. From both towns the information is intermittent, but the disease would appear from the latest intelligence to be maintained, the daily number of deaths varying from 1 to 4 at Trieste and from 1 to 6 at Fiume. Trieste is, however, stated to be much more free than hitherto from the conditions favourable to the spread of the disease, great activity having been displayed by the sanitary authorities. During the week there was rumour of an appearance of cholera in villages in Hungary. So far, no confirmatory news as to this has been received, and it is to be hoped that the rumour was incorrect, for there are many portions of Hungary that could not withstand the importation of the cholera contagium. From Italy we learn that in several of the localities hitherto affected there has been a diminution in the number of cholera cases and deaths; and if we may judge by the published returns, this would appear to be correct, especially as regards the province of Brindisi and the adjoining neighbourhood. In Brindisi town, however, two or three deaths occur daily, and in Francavilla Fontana the fatal attacks have day by day varied from 1 to 4. Other towns, such as Latiano, are also still affected; and, lastly, 26 cases and 9 deaths are reported from Manduria. In the north, the returns as to the city of Venice came to a somewhat suspicious termination two or three days before the departure of the King and Queen for that place, but in the province of Venice the disease still continues. Thus, 42 cases and 20 deaths are reported as having occurred there in the forty-eight hours ending mid-day on July 26th. In the neighbouring province of Ferrara a considerable diffusion

n the area affected occurred about July 23rd, the towns of Comacchio, Massafiscaglia, Porto Maggiore, Copparo, and Pieve di Cento, nearly all lying close to the swampy sea nlet on the eastern coast of the province, being implicated; nd a few days later intelligence was received that the lisease had also appeared in the provinces of Treviso, Vicenza, Padua, and Udine, as many as 128 fatal cases occurring in forty-eight hours. In the city of Bologna, too, 4 cases and 7 deaths took place during the same period. Thus, whilst a diminution may have taken place in localities previously infected, the area of distribution of the disease has been materially widened, and this in the face of an ntense heat. The most hopeful sign is the diminution we have referred to as having taken place in the south, where he heat is exceptional in its intensity.

THE CHOICE OF DIRECT REPRESENTATIVES.

WE are glad to notice the absence of any indications of undue haste in the selection of candidates for the Medical Council. The reasons for much consideration are clear, and have been already stated. The most obvious of these is the disproportion between the number of places to be filled and the number of fit persons for them. In every county of England, Scotland, and Ireland there are many men whom we should like to see elected, and whose judgment and experience would be a valuable element in the deliberations of the Council. But five only can be chosen to represent 26,000 practitioners. As the representation can only be small, it is desirable that it should be real. All are agreed that the official, the consultant, and the teaching elements are already fully represented in the Council. What is conspicuous is the absence of the general practitioner or of members of the profession who have shown themselves in real touch and sympathy with him. Those who have worked hardest and most effectually for the direct representation of the profession should now combine to secure the supply of this want in the Council. The regulations for the conduct of the election are not yet published by the Privy Council. We shall not fail to give our readers early intimation of their tenour. Meantime, it is important that the profession in different parts of the country, roughly perhaps in England dividing itself into different electoral areas, as is already done for Scotland and Ireland by the Act, should give some sign of its disposition in the matter of persons. We shall be glad to receive early information in this direction.

SYPHILITIC CHOREA.

A YOUNG MAN in Buenos Ayres, who by his strange contortions had excited the curiosity of the passers-by, recently came under the care of Dr. Franceschi, who was somewhat puzzled by the symptoms. The movements were of a choreic nature, the most characteristic being a contortion of the thoracic abdominal and pelvic muscles. The patient's condition became so grave that he could not move out of his room. For a month various methods of treatment were unsuccessfully employed—electricity, sulphur baths, strychnine, hyoscyamine, &c. A consultation was then arranged with Drs. Valdes and Alcorta. The first of these gentlemen remembered having treated the patient six months previously for a chancre, which at the time was not thought to be syphilitic, and had not been treated by mercurials. There were no enlarged inguinal glands or other marks of syphilis; however, it was decided that the chorea might be of syphilitic origin, and therefore Ricord's pills (green iodide of mercury), inunction over the spine of a mercurial and croton ointment, together with Van Swieten's solution (perchloride of mercury) and vinum ferri, were prescribed. In three days salivation occurred, and simultaneously with it the choreic convulsions disappeared. The mercurial treatment was then discontinued, but it was found necessary to resume it, for the convulsions soon began to recur. The salivation subsequently became so distressing that the mercury was again stopped, and the convulsions returned, though not so severely as before. Mercurial and iodide treatment was continued for six months, at the end of which time the patient was completely cured. Dr. Franceschi considers this case especially instructive, as, though various predisposing causes are usually named in connexion with chorea, neither syphilis nor mercurial treatment is mentioned, as far as he can find, by Bouchut, Graves, Jaccoud, Diday, Tardieu, or Trousseau. It has, on the contrary, been stated that mercurialisation may act as a factor in its etiology; here, however, is a case in which mercury cured it. The author seems to think that perhaps a hereditary syphilitic taint may sometimes have some effect on the development of chorea, and that, if so, mercury would be the best form of treatment to adopt.

FLUSHING DRAINS WITH SEA-WATER.

WITHIN the last decade Yarmouth has succeeded in reducing its annual death-rate from 23·02 to 19·03 per 1000, and its zymotic death-rate from 4·6 to 2·28. This is a great success considering the difficulties presented to the authority by the natural disadvantages of the situation, and the fact that Yarmouth is a commercial town and port as well as a health-resort. The difficulties of the site, as pointed out by our sanitary commissioner who visited the town in 1875, consisted chiefly in the perfectly flat nature of the district, rendering it difficult to get sufficient fall for the drainage, and impossible to discharge the sewage at points above sea-level. These two factors led at that time to considerable damming back of the sewage matter, and at times to tremendous pressure of sewer air within the sewers and house-drains. The earliest action of the sanitary authority was to relieve as far as possible this dangerous condition of things, first by the free erection of ventilating shafts in those parts of the town in which the pressure of sewer air was most felt, and then by endeavouring to prevent the deposition of sewage within the drains themselves by means of constant and systematic flushing. The cost of this flushing with fresh water is of course considerable, and we are pleased to find that a scheme has been suggested, and is likely to be carried out, whereby the sewers will be flushed by means of sea-water to the amount of 25,000,000 gallons annually. Automatic flushing-tanks containing 1500 gallons will be placed along the main thoroughfares and daily discharged into the sewers, whilst provision is also made for watering the streets in the central parts of the town by means of hose, as in Paris and Brussels. It is estimated that about 160,000 gallons of water will thus be passed through the sewers each day during the height of the season. When this scheme is thoroughly carried out we shall no doubt find the death-rate decline still further. One of the elements of the old high mortality of this town, however, still continues, and that is the excessive mortality amongst illegitimate children. Like all seaports, the illegitimate birth-rate at Great Yarmouth is high, and among these unfortunates under one year of age there is a death-rate of 32·9 per cent. How many reach maturity it is difficult to say, but that this mortality is caused by any special unhealthiness of the town is contradicted by the fact that the death-rate among children of more happy parentage was only 12·8 per cent. The sanitary authority having pointed out the existence of this blot on the town, it is only necessary that steps should be taken to remedy the evil, for it is undoubtedly one cause of the death-rate of Yarmouth being higher still than it should be, and in these days of sanitary competition no watering-

place can afford to lose a point in the game. The sanitary authorities are deserving of every credit for what they have already done, and in inaugurating a system of drain flushing and street watering with sea-water they are setting an example to other seaside resorts.

THE PRINCE OF WALES.

THIS nation is especially happy in its princes. The lamented Consort of our gracious Queen set a noble example of active concern for the happiness and prosperity of the people, and his sons are walking in his steps. The Prince of Wales, not simply as heir to the Crown, but as the first of English gentlemen, has made it the business of his life to strive by every means in his power to promote the enlightenment and progress of the Queen's subjects. It would be fulsome, and might be mistaken for mere adulation, to set down all we honestly feel, and what we are sure the masses of the population feel, on this subject. We do not believe there is a more genuinely popular man in the country, apart from his illustrious rank, than the eldest son of our august Sovereign, and for the very reason that the people in their hearts know that he really loves and cares for them. His Consort gracefully shares his labours, and her endeavours are loyally and lovingly appreciated. It is therefore with great satisfaction that we observe the inauguration of a movement, originating with a few actively benevolent and enterprising men who have participated in the Prince's care for the people, to make some suitable acknowledgment, in the shape of a testimonial, of the services rendered by the Prince of Wales to the peaceful, domestic, and commercial interests of the country. The movement has taken its rise in connexion with the Indian and Colonial Exhibition, which we owe directly to the thought and enterprise of His Royal Highness, but it should be understood that this great service rendered by the Prince to the people is only the culminating point in a long course of active endeavours for their good. We most heartily wish the movement success, and we trust it will reach proportions worthy of its object, and making it a fitting expression of the people's will. The following noblemen and gentlemen have been named as a subcommittee to carry out the details of the scheme: Earl Cadogan, Earl of Rosebery, Field-Marshal Lord Napier of Magdala, G.C.B., G.C.S.I., the Lord Mayor of London, the Right Hon. Sir John Rose, Bart., G.C.M.G., and Sir Robert G. W. Herbert, K.C.B.

THE LONDON CONVALESCENT HOSPITAL.

ACTIVE steps are being taken to carry out this scheme (inaugurated at a Mansion House meeting last year), which is a comprehensive measure dealing with the want which is very generally felt for an increase of accommodation for the convalescent poor and working classes of London and its suburban neighbourhood. A special feature of the movement is that ample provision will be made for a very large class of patients at present wholly unprovided for—that is to say, for those who, recovering from sickness or accident, still need a continuance of medical or surgical aid. The administration of the hospital will be carried on with the practical assistance of gentlemen of the medical profession connected with the leading London hospitals, who have already taken a prominent part in the deliberations of the Council, which is composed of a large number of the influential clergy, doctors, and laity of London, and is under the direction of Earl Cowper as chairman, Sir Spencer Wells as vice-chairman, and Sir J. Risdon Bennett as chairman of the Executive Committee. An essential principle in the constitution of the institution is that every encouragement should be given to the working classes to assist themselves as far as they are able, and consequently, as a general rule, a small weekly payment will be exacted from the patients; on the other hand, careful provision has been made for the free admission of those who from extreme poverty are entirely unable to help themselves. Before making any public appeal for funds, it has been thought better to secure the support of such among the wealthy and influential who might be found to approve the scheme, and already very liberal donations have been promised.

IMPORTANT JUDGMENT AS TO PRIVY NUISANCES.

MR. ILIFFE opens his annual report for 1885 by stating an important case recently decided in the Court of Queen's Bench. The justices of Derby had made an order that certain privies which were a nuisance should be dealt with in a specified manner, so as to avoid the recurrence of the nuisance, and the appellant appealed on the ground that he was prepared to abate the nuisance in his own way, and that this was all that the justices had power to order him to do. Mr. Justice Day, however, pointed out that the justices could order works to be done in compliance with the requisition of a notice "or otherwise to abate the nuisance," and the justices had acted on the alternative. They were clearly in no way bound to allow the person complained of to do only that which he might think fit to abate the nuisance. So, also, Mr. Justice A. L. Smith held that the justices had power under Section 96 of the Public Health Act to order structural alterations, and negatively it had been decided that they were not obliged to give an alternative to the person complained of, so that he might abate the nuisance in his own way. The appeal was therefore dismissed. In the case in question the justices had ordered the appellant to convert the privies complained of into proper pan waterclosets, and to connect them with the main drains, and this requirement has, quite apart from the appellant's ability to remedy the nuisance in any other way, been upheld as legal, and has hence to be complied with. Very similar circumstances had already been brought before the Queen's Bench in a previous case, and with the same result, but this case will probably settle the matter finally, and in towns where the authorities are convinced that a nuisance can only be remedied in a certain way, they have only to issue a notice specifying the manner in which the works are to be executed, and to prove their requirements to be well founded, in order to procure an order directing the execution of the actual works which they have specified as necessary to prevent the recurrence of the nuisance. The case will be known as that of Whitaker (app.) *v.* Derby U.S.A. (resp.).

PUERPERAL TETANUS.

DR. W. NETZEL mentions in the *Hygeia* a case of puerperal tetanus. The patient was a woman of twenty-five, a primipara, who was brought to the lying-in hospital by a midwife a day and a half after labour had commenced. The fœtus was dead, and its large head locked in the pelvis. The os uteri was 5 centim. in diameter, thick and rigid. Perforation was resorted to. The fœtus and placenta were expelled spontaneously five hours later. The cavity of the uterus was washed out with a 3 per cent. solution of carbolic acid. The temperature rose on the fourth day and the lochia became putrid. Intra-uterine injections of a 3 per cent. solution of carbolic acid were used, and the vagina was washed out with sublimate. On the eighth day trismus and stiffness of the neck appeared. The following day there was stiffness in the shoulder and spasmodic contractions of the facial muscles, with painful spasms. The temperature was 41° C.; pulse 140. The woman died at mid-day. Chloral had been given and subcutaneous injec-

tions of morphia and curare. On making a post-mortem examination, an ulcer was found in the cervix reaching through the uterine walls to the peritoneum. There was parenchymatous degeneration of several organs. Dr. Netzel considered the tetanus in this case to be a symptom of general septic infection.

DRINK IN THE BUILDING TRADE.

THE modern practice of erecting in our principal cities huge buildings with iron columns and girders of many tons' weight necessarily entails commensurate risks on those who are engaged in the works. Cranes and derricks, self-stopping pulley-blocks, and thoroughly tested chains, while economising labour, tend to minimise the number of accidents, but also to aggravate their destructive power when they do occur. It is truly wonderful to see a granite pillar or an iron girder lifted and swung round over any part of a building area, and then deposited accurately and smoothly on any given point with singularly little help from comparatively few men. But how necessary that every one of them should be at his best, cool-headed and steady-handed. When a crash does take place, the explanation is generally found in some flaw in the machinery; but it is to be feared that every now and then an oversight or a slip on the part of one of the men may be the first cause of the break-down. It is only just to bear in mind that the building trade is a very laborious one, and that a large proportion of the men engaged in it are distinguished amongst artisans for intelligence, sobriety, and thrift. But just as the strength of the chains and ropes employed is only equal to that of the weakest link or strand, so at a critical moment the efficiency of a band of workers is only equal to that of the individual man; one failing may imperil all. Dust and labour, often over-long hours in working under contract against time, make men thirsty and tired; and if anyone watches a great building, he often sees men slip out for a drink at the nearest public-house. It is only occasionally that the building area can be completely enclosed and placed under the charge of a trusty gatekeeper, but something might always be done to provide the men on the ground with cooling and invigorating drinks. Cocoa, lime-juice, or oatmeal could be dispensed for a comparative trifle, and, failing these, a large water-filter and a few earthern cups might be a great comfort, and avert the temptation of rushing to the beer-barrel and the spirit-vat with a parched tongue and an empty stomach. The men, timely refreshed, would work longer and with greater power and safety, and when an accident did happen, as may sometimes be unavoidable, it would be a satisfaction to feel that at the critical moment every man was at his best, mentally and physically.

BACTERIOLOGY AT BRIGHTON.

AN extended illustration of bacteriology will be given this year at the annual meeting of the British Medical Association in the section of Public Medicine. The arrangements have been entrusted to Mr. Edgar Crookshank, and the result will doubtless interest many who have not hitherto had an opportunity of acquiring some practical acquaintance with this interesting branch of science. The demonstrations will be held in the spacious building of the School of Science and Art, and the rooms will be open from 10 A.M. to 1 P.M. on August 10th, 11th, 12th, and 13th. In Room A there will be an exhibition of bacteriological apparatus. A complete set of apparatus of the German pattern will be supplied by Becker and Co. Sterilisers, incubators, and various apparatus of English make will be shown by Messrs. Griffin and Son. Microtomes and histological apparatus will be exhibited by Messrs. R. and J. Beck; and the list will be completed with apparatus and materials supplied by Mr. Crookshank. In Room B there will be a demonstration of some sixty cultivations of micro-organisms in various media. Dr. Penrose will assist in the preparation and demonstration of the cultivations. In Room C there will be a demonstration of preparations of bacteria and other micro-organisms of pathological interest under about fifty microscopes. In addition to assistance from private sources, the latter will be supplied by the following firms: Mr. C. Baker of Holborn (with immersion objectives by Zeiss, Reichert, and Leitz); Messrs. Surft and Son, who will also show their new lamp for high power work; Messrs. R. and J. Beck; and Messrs. Powell and Lealand. In Room D there will be shown photo-micrographic apparatus, and a large collection of photographs of bacteria and other micro-organisms taken by Mr. Crookshank. The photographs comprise silver, ferro-prussiate, platinotype, and Eastman bromide paper prints autotype reproductions in special colours, original negatives transparencies, and enlargements.

M. PASTEUR'S CRITICS.

Room for criticism of M. Pasteur's prophylactic method of treatment of hydrophobia unquestionably exists, and has been freely occupied. Several writers of eminence have taken up strong positions against the method. The British Hydrophobia Commission may be, in a sense, regarded as a critic. At home and abroad, criticism, not always tempered with good judgment, has been hurled at the head of the renowned Pasteur. The proper attitude to adopt is one of simple watching and waiting whilst those most qualified to investigate and judge are examining the methods and observing the results of the treatment. Men really competent to decide on the methods and results are, we think, few in number, and must be so, for the investigation requires certain skill and knowledge which have had to be acquired at the cost of much assiduity during the past few years, since this department of high pathology is of recent growth. At the same time, we do not wish to imply that any scientific man of common sense should not be allowed to consider the logic of the matter. Mr. Vincent Richards, in an able pamphlet which has just reached us, has exhibited great shrewdness of argument in his criticism of M. Pasteur. But whilst we admire the force of Mr. Richards' logic, made more valuable by his scientific attainments, we cannot but think that his language is scarcely temperate and his arguments not conducive to the advancement of science.

SANITARY BURIAL.

A PAMPHLET by Mr. Frederick Lowndes on Burial Reform in and around Liverpool deals in a concise but instructive manner with the leading points of this important question. Statistics which are quoted with reference to the space available for interments in the various district cemeteries are sufficient to justify the statement that it is at least highly desirable that ground for burial should be economised. It naturally follows that methods now in common use, including the massive coffin, whether of lead or oak, and every form of vault, receive from the author a common condemnation. He is, we are pleased to note, an uncompromising advocate for the earth-to-earth system of burial. By adopting this plan, with due allowance of time for the free action of decay, it should be possible to use one grave for the successive interments of several dead persons without any risk of unwholesome consequences to the living—a point which is also brought out in the present paper. While acknowledging, however, the general fitness of the earth as man's last resting-place, provided only that no ponderous casing intervenes, Mr. Lowndes has evidently a leaning towards cremation. We do not quite follow him when he asks for this process a permissive legality. Such a standing has

already been assigned to it. What it still lacks is the direct approval of law. This, it has been often contended, should be allowed on the mere guarantee of certification of the cause of death. With such an opinion we cannot agree, nor can we admit that the post-mortem evidence of crime is to be made little of because, in the words of this paper, it is merely corroborative. It is difficult to see how it should form the first step in a judicial inquiry, but this does not impair its great value in confirming or opposing an established suspicion.

BRIGADE SURGEONS IN INDIA.

ALTHOUGH we cannot agree with all the statements put forth by the brigade surgeons in India in their claims to consideration, we think they have really good reason to complain that they have been unfairly treated. While the rank has been nominally recognised, the advantages of increased pay and allowances have been withheld. The change from the regimental to the station hospital system was the means of effecting a very considerable pecuniary saving to the Indian Government, but it was attended with increased responsibility and additional work on the part of the medical officers in charge of these hospitals. For this, however, no compensation has been given, nor has any addition been made to the pay, allowances, or pension of the officers on whom this charge has devolved. In the present state of Indian finance it is essential that every legitimate economy should be practised; but this does not justify throwing upon officers increased work and responsibility with reduced allowances. The change of system deprived medical officers of the allowances for being in charge of regiments, and added very materially to the work of those in charge of hospitals. Surely, then, some part at least of the saving effected in the one case should be applied to compensate for the increased labour and responsibility involved in the other. It is unfortunate, in our opinion, that the officers who have drawn up a "statement of claims of brigade surgeons" did not confine themselves to these real grievances, for we cannot but think that they have weakened their position by the introduction of exaggerated statements regarding the system of promotion by selection and the nature of the examinations which surgeons-major are required to undergo previous to selection. The medical officers have a very strong claim for "a staff allowance" when in charge of a station hospital, and there is no lack of precedents for such an allowance being granted when a change in departmental arrangements has carried with it, as in the present instance, much additional work and increased responsibility.

VERY LARGE BILIARY CALCULUS.

DR. ARTHUR HASSALL was recently called in consultation, in conjunction with Mr Edward Newton, by Dr. Martemucci, of San Remo, to a case of intestinal obstruction. This obstinately resisted all modes of treatment for some days, but at length a copious evacuation was obtained; this was fortunately carefully examined, and in it a large stone-like body was found. It was smooth and polished on the surface, of a brown colour and of an ovoid form; it was 44 millimetres (1·73 in.) in length, and 23 millimetres (0·90 in.) in diameter. It weighed 16 grammes (247 grains), but the weight was not taken till a day or two after it was voided, when it had become considerably lighter from the evaporation of contained water. When broken into, it was found to be colourless, transparent, and beautifully crystalline, the crystals being concentrically arranged. On analysis, it was ascertained to consist entirely of cholesterine. The patient was at no time jaundiced, although the urine contained bile acids. The remarkable points of this case are the magnitude of the calculus, and the fact that it actually gave rise to obstinate intestinal obstruction. Cholesterine is readily affected by heat, and Dr. Hassall has thrown out the suggestion that possibly the escape of the calculus from the cystic duct might in such cases be facilitated by the slight softening and consequent moulding occasioned by the prolonged heat to which it was subjected while in the body.

EXTENSION OF TEMPERANCE.

WE have repeatedly had occasion to notice the papers of Lady John Manners on social subjects. Few ladies do more good or make more useful contributions to the arguments for simple, sober, cheerful habits. The *Church of England Temperance Chronicle* contains a short but very sensible article on "The Gradual Extension of Temperance Principles and Societies," arguing chiefly against the use of brandy and other stimulants by women for slight attacks of indisposition. Lady Manners has lived much in Germany, and says that an intelligent German woman, who for many years has known English people of all classes, said to her, "There's one thing surprises me: English women, if they do not feel well, so often take brandy. We have no such custom. We think it must make them worse." The habit of taking a little alcohol for the relief of various sensations is certainly less common among intelligent women than it used to be, but it is still too much so. It cannot be too much condemned. The use of hot tea or coffee and of hot applications is infinitely wiser. We commend Lady Manners' paper to all readers. She remarks, on the subject of Army Temperance Work, that the German Government does not provide its soldiers with beer, wine, or spirits, and that they are remarkably sober. Thanks to such men as the late and ever-to-be lamented Dr. Parkes, and Lord Wolseley, we are much more chary now of giving our own soldiers stimulants, and with much advantage.

THE RIVER LEA.

STATEMENTS in the public press bear witness to the fact that the condition of the river Lea below the sewage works at Tottenham is greatly improved. The recent agitation has not, therefore, been wanting in success, and the result shows sufficiently clearly how much can be done by local authorities when they are compelled by public opinion to exercise the powers they possess. Major Flower, the engineer to the Lea Conservancy, has, in a letter addressed to Mr. Hanson of Wakefield, expressed on behalf of his board their "unqualified delight at the changed condition of the river Lea" below the sewage works at Tottenham. This improvement he attributes to the method devised by Mr. Hanson of treating the Tottenham sewage by black ash waste. The effluent from the Tottenham sewage works still flows into the river, but its condition is entirely changed, and it is stated to be free from any secondary decomposition.

LONDON DUSTBINS.

THE *Engineer* pleads for a more frequent removal of house refuse during the hot weather than once in every fortnight, and comments on the complaint of a correspondent that the use of a galvanised iron receptacle adds to the offensive condition of its contents. It suggests whether decomposition is not favoured by the closeness with which the refuse is packed and the greater heat of the foul atmosphere in the metallic box. This objection does not appear to be well considered; there is no reason why the refuse should be more closely pressed together than in a larger dustbin; the limitation in the size of the receptacle simply indicates the need for more frequent removal; and if the metal has a

tendency to become heated, this is guarded against by placing it in some position where it is not exposed to the direct rays of the sun. Metal dustbins have one marked advantage over brick: the porosity of the latter causes them readily to absorb the moisture and gases given off by the contents, and the dustbin under these circumstances becomes itself a source of nuisance. Our own opinion is certainly that the impervious material of which metal dustbins are made, and which enables them to be movable, is far more advantageous to health than the fixed brick dustbins, of which London now possesses too many.

EQUIVOCAL CAUSE OF DEATH.

ON July 14th an inquest was held at St. George's Workhouse, Buckingham Palace-road, concerning the death of a flower-girl, named Ellen McCormack, aged seventeen. Deceased left her home to follow her avocation on July 10th at 5 o'clock in the morning, and at 2 in the afternoon she was discovered by the police sitting on some steps, speechless and "apparently drunk." A medical man who passed by is reported to have said she was intoxicated. On being taken to the police-station the divisional surgeon's assistant found her in a dying condition. At the post-mortem examination no alcohol was detected in the stomach. The lungs were much congested. Death is said to have been due to mucus lodging in the windpipe during the act of vomiting. The father of the girl deposed that she had been a teetotaller all her life. As regards the immediate cause of death, there seems little doubt it was from suffocation; but the question naturally arises, How was the congestion of the lungs brought about? To say the least, it is rare for a person to die from mucus passing into the windpipe whilst vomiting, unless at the time there was something to interfere with expectoration, such as narcotism, or some mechanical impediment to the clearance of the air-passages. If the girl had taken alcohol in excess the matter would have been easy of solution, especially as she was unaccustomed to the poison. We do not lay much stress on the statement of the policeman that the vomit smelled like alcohol, since the odour of the contents of the stomach is apt at times to mislead even experienced practitioners. We should like to know upon what grounds the doctor who first saw the deceased based his conclusion that the latter was drunk. Without accusing anyone of blame in the matter, we cannot help thinking that the case may have been one of vomiting caused by some acute disease—e.g., pneumonia. The jury were practically bound to return a verdict in accordance with the medical evidence. This verdict may have been a record of the truth, but from the information at present before us we cannot help expressing our mistrust. If the testimony of the parents of the deceased can be relied upon, it seems strange she should have taken a fatal dose the first time she tasted alcohol.

HYSTERECTOMY AND NEPHRECTOMY.

La Gazzetta degli Ospitali (July 21st) reports a successful operation by Professor Calderini, of Parma, for the removal of the entire uterus. The organ had been completely prolapsed for some time, and was the seat of multiple subperitoneal myomata. The temperature after the operation never exceeded 37·7° C. Of six vaginal hysterectomies, four were successful in the hands of Professor d'Antona of Naples. This operator has devoted much attention to renal surgery. He prefers lumbar to abdominal nephrectomy, and thus summarises the statistical results of the two operations up to this date. In 111 lumbar nephrectomies the percentage of mortality has been 39·93, whereas the abdominal method practised 120 times is said to have yielded a death-rate of 50·83 per cent.

QUALIFICATIONS IN SANITARY SCIENCE.

THE first annual meeting of the Society of Medical Men qualified in Sanitary Science has been held, and the President, Sir Joseph Fayrer, has delivered an interesting address, of which we print a summary in another column, and which will give an impetus to the new Association. A great success has already been achieved by the Society in obtaining the registration of Sanitary Science qualifications; the members are now engaged in the promotion of the second of their objects, the obtaining of better recognition of the value of such qualifications as an evidence of special knowledge in the department of public health by the various sanitary authorities. Their desire is praiseworthy, for the circumstances which often lead authorities to elect health officers are not always those which imply the promotion of sanitary work in their districts; if people can be taught, as we hope they may, by the slow process of education, that a skilled and energetic officer is of value to the community, the newly formed Society will have conferred a great boon upon the public.

THE POPULATION OF PARIS.

THE rate of increase of population does not appear to be governed by any fixed laws. Paris has only added 16,000 to her population in the course of five years. Is this a matter for congratulation or the reverse? Looking at the state of poverty in the gayest city in the world, we think that Paris is to be congratulated on her want of fecundity. But, regarded in another light, this slow increase may not be a favourable condition. A population that neither increases nor diminishes may be vigorous and capable of holding its own in the international struggle of existence, but the chances are against this supposition. Excessive fecundity, on the other hand, may not be a spring or sign of strength. Too rapid growth taxes the resources of a nation, and may prove too much for them, thus becoming a source of weakness. A large population of sickly or puny individuals living in a fertile country would soon be exterminated; for unopposed strength knows no peaceful international laws. The slow increase of population in Paris need excite no apprehension if the health of her individuals is not below the normal. Indeed, nothing can be learnt from the mere rate of growth of a population as to its state of health. Moreover, we cannot judge accurately of the strength of a nation by the state of its urban population. Fluctuation is rampant in the metropolis of most countries; the numbers may remain the same. Cities are characterised by the presence of the greatest and hardest workers, and any falling out of the ranks of these is quickly replaced by those who can take their place.

THE PECULIAR PEOPLE.

WHEN one of the Peculiar People has a child, which its own father describes as a peculiar child, the force of peculiarity can scarcely be carried further. When the unlucky child, in addition to the misfortune of having for its father one of the Peculiar People, has to run the gauntlet of the following diseases—measles in January, whooping-cough afterwards, followed by low fever, this succeeded by diarrhœa, and, a week afterwards, convulsions,—we do not need to assume much "peculiarity" in the child to account for its death, either by meningitis, as Dr. Jones of Blackfriars-road said, or any other lesion. The shame is that a poor child should have to go through all this without the benefit of medical help. Dr. Jones may be quite right in saying that meningitis—we presume tubercular—is incurable; but he will not deny that, if the child had had the benefit of medical advice for its measles in January and its later ailments, the chances of the occurrence of menin-

gitis might have been diminished. The jury quite approved of the censure and warning expressed by the coroner. It is to be regretted that the parent was not committed for manslaughter. This is the only way to get such people to realise the gravity of their neglect and stupidity.

THE DARLINGTON HOSPITAL.

WE regret to learn from statements in the local press that serious difficulties have arisen in connexion with the management of the Darlington Hospital. It seems that for some time past there have been disagreements between the medical staff and the matron, and that a majority of the Executive Committee has so managed affairs that the entire honorary medical staff has resigned. We are not in a position to enter fully upon the points in dispute, but the pass to which matters have been brought is of itself a heavy condemnation of the management of the hospital. It is stated by the late senior physician that his patients did not receive the diets he ordered them, and that many of them left on account of the improper and insufficient food they received. Complaints made by the staff are stated not to have been fully or impartially investigated. Nurses and servants have found their positions untenable or have been dismissed, and the house-surgeon has been discharged in a peremptory manner. We hope the subscribers to the hospital will insist on taking whatever steps may be necessary to prevent a recurrence of such a state of things. Without wishing to insist unduly on the weight that should be given to the advice of the medical staff; we must assert that the two essentials of every hospital are patients and doctors, and that the managing committee, nurses, and lay officials are all subsidiary. The full recognition of this fact ought not to lead to any jealousy on the one hand, or to any overbearing conduct on the other, and it is the key to the successful conduct of a hospital. The supporters of the Darlington charity may be sure of this, that the greatest loss the hospital can sustain is the loss of experienced and able medical officers.

MEDICAL EDUCATION IN CHINA.

THE difficulties in the way of educating the natives of China to any satisfactory degree in the knowledge of scientific medicine are very great, involving the dispossession of their minds of the crudities and absurdities of their traditions on such matters, the necessity of instructing them in one of the European languages in which there is a medical literature, and the securing of clinical opportunities—to say nothing of the task of cultivating in them a truly scientific spirit of inquiry. That the difficulties are as great as represented is evidenced by the fact that even the assistants in the European hospitals in China have never been able to acquire more than a certain manual dexterity. To Dr. Wykeham Myers, the surgeon in charge of the David Manson Memorial Hospital at Takow, Formosa, belongs the honour of an experiment which, if successful, will lead to the replacement by Western medicine of the crude and unscientific system followed by the Chinese professors of the healing art. Some four years ago he endeavoured to found a medical school, in which the student should have a similar education and pass as nearly as possible similar examinations as medical students in Great Britain. After two years of failure Dr. Myers succeeded in his project, and last May he had the gratification of presenting to a board of examiners composed of surgeons of the British army and navy and colonial medical officers, with one native who is well educated in chemistry, two native students, who succeeded in passing a searching examination in anatomy, physiology, elementary surgery, and chemistry: one obtaining 72·6 and the other 70·5 per cent. of the possible marks. Such a result is highly satisfactory, and must amply repay Dr. Myers for his self-denial, labour, and perseverance in the face of obstacles during the past few years; for it cannot be doubted that the school which he has been instrumental in founding will prove the seed which will germinate into a vast reform in China. Of course the grand object is to get the Chinese Government to take over the school. To this end its promoter must steadily work; and doubtless, now that he can show more than promises, considerable headway will speedily be made.

THE POLICE AND THE DOGS.

LOVERS of dogs should not forget their obligations to their fellow-beings. The danger of dogs being at large is not an imaginary one. The report of the Chief Commissioner of Police is worthy of careful perusal. It is not true that the majority of dogs slaughtered by the police were healthy. During the week ending the 10th inst., 17 dogs were killed by the police. Of this number, 5 were actually suffering from rabies, 7 had epilepsy, 2 had some kind of fits, 1 had convulsions, 1 was ferocious, and 1 was not examined. This is the greatest number killed in one week since July 1st, 1885. In the year 1885 the police captured over 25,000 dogs; 365 of these showed signs of rabies at the time of capture; and 60 which did not appear to be mad at the time developed signs of madness after arrival at the Dog's Home, and were then killed. Owners of dogs in London would be doing a kindness to their canine friends if they never allowed their dogs to go for an airing in the streets without some kind of attendance. We yield to no one in our love for the brute creation, but the laws of the country must be obeyed. Surely one human life is of more account than any number of dogs.

VACCINATION IN SWITZERLAND.

THE remission of the law enforcing compulsory vaccination in Switzerland, which was brought about by the clamour of the public, has already begun to bear fruit. The canton of Zurich was during 1881-84 entirely free from small-pox deaths. In the first quarter of 1885, however, there was a small-pox mortality of 6, in the second and third of 14, and in the fourth of 38 per 1000 deaths from all causes. In the first quarter of the present year the small-pox mortality in Zurich was 85. A Berlin journal remarks that it is instructive to compare the small-pox mortalities in Germany and France. During 1885 in twenty-one German towns, where vaccination is compulsory, and where the population is about four and a half millions, there were 27 deaths from variola; while in fifteen French towns with a similar aggregate population, where vaccination is not obligatory, the deaths from the same disease were 866, or thirty-two times as many.

ALLEGED DEATHS FROM VACCINATION.

A CORRESPONDENT of a contemporary claims that vaccination has caused the deaths of two children: the one an infant aged four months, who was vaccinated on June 15th and died of convulsions on July 18th; the other a child, aged five months, who was vaccinated on the 6th inst. and died on the 19th. Both these children suffered from diarrhœa, and in both the medical attendant registered the death as due to this cause. But the children had been vaccinated, and this in the minds of some people is always held to be responsible for any adverse symptom which may occur subsequently to the operation. When it is recollected that the majority of children who are born are vaccinated within the first three months of life, it is inevitable that many children dying at this period of life must succumb *after* vaccination, and thus afford opportunity to those who are opposed to vaccination to quote this operation as the cause of death.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE total amount received at the Mansion House on behalf of the above Fund had on Thursday evening last (including a second donation of £1000 from Dr. Wakley) reached £39,121. As compared with the receipts at the corresponding period last year this sum represents an excess of nearly £5000. It is fully believed that at the meeting of the Council for distribution this (Friday) afternoon the total amount will reach £40,000.

THE LATE DR. MOXON.

BY the death of Dr. Walter Moxon, which occurred suddenly on the 21st inst., the medical profession loses a distinguished leader, a brilliant writer, an eloquent speaker, and an unsurpassed teacher. Esteemed by all with whom he came in contact, his untimely decease is keenly mourned by his professional and private friends. In our next issue we purpose giving a detailed *résumé* of his life and work.

"A BOY WITH CAT'S EYES."

A CASE with this heading is reported as now exciting the attention of the oculists of Chicago. Mrs. Quinn, of 471, Wells-street, recently visited the State Eye and Ear Infirmary in company with her son, who possesses the peculiar power of seeing in the dark. One of the surgeons, Dr. Charles F. Sinclair, called in several other oculists to examine the anomaly. The boy was taken into a dark room, and various tests were applied. The eyeballs glistened like balls of fire. The larger portion of the iris is missing, only a small portion being visible on the outer side of each eye. When taken into a dark room an immediate expansion takes place which enables the boy to see perfectly. A strong light blinds him, and from this same peculiarity the boy is able to see objects at a distance with much more clearness than those close at hand. It seems to be a case of coloboma of the iris and choroid, with defective development of pigment, and perhaps with a hyper-sensitive retina.

"DRUNK OR DYING?"

HOW long will this trite question continue to be a reproach to the police? The circumstances under which it arises have been enumerated *ad nauseam*. The suggestion contained in a letter by Dr. Groth to a contemporary is a valuable one, but hardly practicable. In every case of doubt the individual who has been "run in" should be treated as though his were a case of serious illness, and a competent medical opinion sought and obtained. If the police surgeon cannot be found, some neighbouring medical man should be summoned. Police constables could not be taught how to diagnose drunkenness from other states of unconsciousness; this is a matter often requiring considerable medical skill, and even then not always determinable at first sight.

POISONOUS VEGETABLES.

STRAWBERRIES raised on soil manured with the most offensive material are said to be as delicious as others. Speaking generally, the nature of the soil, provided it be of sufficient richness, exercises little influence on the nature of its vegetable products. Asparagus, however, grown in certain localities in France, has caused those who have partaken of it to suffer from colic and diarrhœa. It was ascertained that the asparagus was impregnated with minute amounts of sulphide of carbon. But the chief wonder is that animal and vegetable life should possess such remarkable powers of discrimination as generally to reject poisonous matter.

TYPHOID FEVER AT LANCING COLLEGE AND SHOREHAM.

AN outbreak of typhoid fever has, we regret to state, recently occurred at Lancing College and Shoreham. An investigation is, we learn, being made into the causes of the epidemic.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of June, it appears that the water derived from the Thames contained in nearly every case rather more organic matter than in the previous month's samples, although the absolute amount present was not excessive and scarcely differed from that found in the same month of last year. Of the water taken from the Lea that distributed by the New River Company was, as regards freedom from organic matter, second only to the best of the deep-well waters, whilst the East London Company's supply ranked in this respect with the best samples of the Thames derived waters. All the samples were clear and bright on delivery.

WE understand that the authorities of St. George's Hospital are making a considerable enlargement of the school premises in connexion with that institution, chiefly for the purpose of providing the necessary laboratories for the teaching of physiology in accordance with the increased requirements of the present day. This department is now placed under the superintendence of Dr. Délépine.

AT a meeting of the Pontypridd Rural Sanitary Authority on the 23rd inst., a serious outbreak of measles in Gilgach Goch was reported, the number of cases being 250. Several of the cases had terminated fatally. A water famine had also occurred in the same place, and the complaints of the inhabitants against the rural authority are bitter.

THE anatomical, zoological, and mineralogical collections hitherto located in the palace of the University of Berlin will shortly be transferred to the new Museum of Natural History, a sumptuous edifice in advanced process of erection in the Invalidenstrasse.

MR. JOHN LOFTHOUSE, a well-known practitioner at Rochdale, died at his residence in that town on the 25th inst. The diseased was a member of the Rochdale Town Council and School Board, and one of the medical officers of the local infirmary.

M. BOUCHARD has managed to induce cataract in rabbits by introducing naphthaline into the digestive canal. The quantity required for the purpose was a daily dose equal to a thousandth part of the animal's weight.

INFORMATION has been received that the sanitary inspection of ships sailing to the United States ports from the port of Liverpool is to be resumed.

THE death is announced of Mr. William Gardner, who for the past half-century has practised in Painswick, near Stroud. The deceased was in his eightieth year.

"FEAR" (*La Peur*) is the subject of an elaborate psychological study by Charles Richet in the *Revue des Deux Mondes* of the 1st inst.

DR. DRESCHFELD will deliver the Bradshawe Lecture at the Royal College of Physicians of London, on Wednesday, Aug. 18th, at 4 P.M. The subject will be "On Diabetic Coma."

DR. JIRUS of Agram has been selected for the chair of Pharmacology in the Bohemian Faculty of Medicine in Prague.

REPORT
OF
The Lancet Sanitary Commission
ON
MARLBOROUGH COLLEGE.

ELEVEN years ago we reported at some length upon the sanitary condition of Marlborough College, and we stated that it decidedly took the lead of certain other public schools with regard to the excellence of its sanitary arrangements. The recent prevalence of measles at the College has led us again to inspect the school; and, in criticising its arrangements anew, it must be borne in mind that medical and sanitary thought have developed in the interval, and that such observations as we have to make will have reference to the views of a more recent time.

There are now 577 boys attending the school, of whom 368 are resident in the school buildings, 198 in out-boarding houses, and some dozen boys, day scholars, living in the town. The buildings, with slight modification, are much as they were when our Commissioner reported in 1875, and, taken as a whole, it may be said that they well answer the purpose for which they are intended. The chief buildings in which pupils resident in the school dwell are known as Houses A, B, and C, House A being occupied by boys under fourteen years of age, who constitute the Lower School; Houses B and C are occupied by boys above this age. In the first of these houses, the number of boys in the different dormitories range from 12 to 16. In the smallest of the rooms, containing 12 boys, there is a floor-space for each bed of 49·5 square feet and an air-space of 569 cubic feet. In the smallest of the dormitories, containing 16 beds, there is a floor-space of 55 square feet and an air-space of 632·2 cubic feet. For the older boys in Houses B and C the dormitories contain from 5 to 22 beds, and the floor and cubic space allotted to each is much the same, but in some dormitories they fall short of this amount by fully 100 cubic feet, while in others the amount is greater. It is noteworthy that the College was inspected by Dr. Bristowe in 1868, when, in a report he presented to the governing body, he commented on the overcrowding of the dormitories which then existed. It will be seen from the figures given above that the allowance of air-space still falls short of that which is thought to be necessary by some authorities, among whom we would mention Dr. Clement Dukes, who recently recommended that the allowance of air-space in dormitories should be not less than 800 cubic feet for each boy. Much attention has been given to the ventilation of the Marlborough dormitories, an arrangement existing in each for the removal of the warmer and vitiated air which rises to the ceiling.

The drainage must be regarded as in a transitional state. Much has undoubtedly been done to ventilate soil-pipes and to disconnect from the drains the wastes of sinks and baths, yet still much remains to be done. The College buildings drain eventually into two brick barrel drains—the one having a diameter of three feet, and which is entirely outside the buildings; the other having a diameter of two feet, and which was formerly outside the buildings, but, owing to the extension of the latter, has now come to pass beneath certain class-rooms, and beneath the Bradleian Hall, where meetings are held. Special precautions have been taken to render this drain impervious; it is bedded in concrete and cement, and the floors of the buildings are made of the same material, over which is placed a closely-boarded floor. After traversing a considerable distance, and after the latter has received the drainage of the head master's house, the two drains meet in a cesspool near the river, situated over 400 feet from the College buildings. This cesspool is divided into two parts, a trap being inserted between the two; from the second of these parts is an overflow into a subsidence tank, from which the effluent escapes into the river Kennett. A ventilating opening is provided for the two-foot drain, but the passage of air is somewhat prevented by the opening being obstructed by a number of trays containing charcoal. The three-foot drain is not ventilated, except so far as it may derive some slight current of air admitted into the two-foot drain and through the cesspool.

The effluent at the time of our visit was discoloured, probably from the drains containing washings from the work which was going on in the building; but the water in its neighbourhood was darkened, and smelt slightly offensively, bubbles of gas escaping to the surface. This part of the river is not frequented by the boys, but some modification and reconstruction was certainly indicated. Within the buildings are only waterclosets used by the boys at night, and one or two by the women in charge of the houses. With the exception of one of the latter and of three for the boys in House C, all have direct external ventilation. A few of the fittings are of the old pan form, and are awaiting removal. As already stated, the more effectual ventilation of the soil-pipes, by carrying them above the roof external to the building without diminution of their calibre, is being done, and work for this purpose was being carried on at the time of our visit. For day purposes the boys use in common a number of waterclosets and urinals, the former of the trough kind, situated outside the building, and connected with them is the necessary machinery for flushing. The drainage of the sanatorium is entirely distinct from that of the other buildings; the drain passes into a cesspool in its proximity, and from this there is an overflow into the town drain. The arrangements here are open to some criticism: first, for the reason that the cesspool is unventilated, and there does not appear to be any trap in the drain which runs into it; and, secondly, because the ventilating-pipes from the soil-pipes are situated within the building, and there is some uncertainty as to whether the bath and sink wastes are disconnected before entering the drain. Before leaving the subject of drainage, reference must be made to a cesspool receiving the drainage from a watercloset near the laundry, and which is situated within thirty feet of the well which supplies the whole school buildings with water. Precautions have been taken to make this cesspool water-tight, but it must be admitted that a receptacle for the retention of excremental matter should not be in this situation. The water-supply, apart from this, is excellent: the well is over twenty-six feet deep in the chalk, and the supply is abundant, the water being pumped into a reservoir on the top of a neighbouring hill, whence it is distributed to the various houses.

The sanatorium, of which the drainage has been described, consists of a number of rooms having from two or three to seven beds in each, and providing accommodation for forty boys and, if necessary, a few more. The rooms open into common passages, and for this reason it is not conveniently arranged for the treatment of more than one kind of infectious disease at the same time. The waterclosets open directly into these corridors, and have no intervening chambers; the fittings in some require alteration, for they are of the old pan kind. In the basement is a disinfecting chamber, containing an oven heated by gas, which is not self-regulating. The disinfecting arrangements cannot be considered complete, for there is no separate provision for the washing of the infected linen; such linen is placed at once in a tank containing a disinfectant, and precautions are taken in its manipulation in the general laundry.

Reference must be made to the out-boarding houses in which many of the boys are resident; these are each in the occupation of a master, three of whom take charge of fifty boys each, the others of smaller numbers. Generally the houses resemble each other, and contain good-sized dormitories, small studies for the use of the boys during the day, and an excellent room in which they take their breakfast and tea, dinner being served in the hall of the College. The soil-pipes here are situated within the buildings, but steps are being taken for the alteration of their position. The drains pass into cesspools in the gardens, having an overflow into the river.

It would be improper to omit mention of the excellent gymnasia in connexion with the College and out-boarding houses, the fives-courts and racket-courts, and the opportunities for bathing afforded by a large pool of running water in the College grounds; this is really part of an old moat, to which water has been laid on from some distance up the river, and where every boy is taught to swim.

The care of the boys themselves is of the best, their sports are shared in by the masters, and every effort is made to preserve a healthy tone amongst them. They are under the constant supervision of the medical officer, Dr. Penny,

whose personal knowledge of each boy and his requirements is an important factor in the preservation of their health; constantly in their midst, he is able, as at the time of our visit, to restrict from too severe exercise a boy who has just recovered from some ailment, and to enforce the warmer clothing of another who has but recently left the sick room.

Much may be said for Marlborough College; it has not, however, entirely remedied the faults of construction of all its older buildings of thirty or forty years ago, and especially does its drainage fall short of such perfection as is now aimed at by institutions which would have their means for the excremental refuse regarded as models—such perfection as may be said to be typically represented in the London Fever and Homerton Hospitals. For this purpose the governors would do well to seek advice. The College has for some years been fortunate in its freedom from scarlet fever, diphtheria, and enteric fever; diphtheria is never known to have occurred there; of enteric fever, one boy only is said to have suffered, and in this instance the disease was not contracted at school. Since an outbreak of scarlet fever in 1877, only one case, we are told, has occurred. This record speaks well for the healthiness of the school, and it certainly behoves the school authorities to see that this reputation is maintained.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5728 births and 3521 deaths were registered during the week ending July 24th. The annual death-rate in these towns, which had increased in the preceding five weeks, from 16·8 to 19·7, further rose last week to 20·2. During the first three weeks of the current quarter the death-rate in these towns averaged 19·4 per 1000, and was 1·3 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 7·8 in Wolverhampton, 13·1 in Derby, 14·0 in Bradford, and 14·2 in Hull. The rates in the other towns ranged upwards to 23·7 in Preston, 24·2 in Manchester, 24·3 in Leicester, and 24·6 in Birkenhead. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding six weeks, under the influence of the rising mortality from infantile diarrhœa, from 263 to 652, further rose last week to 754; they included 505 from diarrhœa, 80 from measles, 66 from whooping-cough, 36 from "fever" (principally enteric), 36 from scarlet fever, 25 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Derby; while they caused the highest death-rates in Portsmouth, Cardiff, and Preston. The mortality from diarrhœa showed a further general increase, the largest excess occurring in Leeds, Leicester, Cardiff, and London. Measles caused the highest death-rates in Portsmouth and Preston; whooping-cough in Halifax and Preston, and "fever" in Brighton and Cardiff. The 25 deaths from diphtheria in the twenty-eight towns included 11 in London and 8 in Birmingham. Small-pox caused no death either in London and its outer ring, or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had been 12 and 13 on the preceding two Saturdays, had declined to 11 at the end of last week; 2 cases were admitted to these hospitals during the week, against 3 in each of the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 197, 190, and 167 in the preceding three weeks, further declined last week to 162, and were 31 below the corrected average. The causes of 74, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Portsmouth, Brighton, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Derby, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·1 and 19·2 per 1000 in the preceding two weeks, further rose to 19·8 in the week ending July 24th; this rate was, however, 0·4 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·1 and 14·8 in Leith and Perth, to 23·5 in Glasgow and 26·0 in Paisley. The 489 deaths in the eight towns showed an increase of 14 upon the numbers in the two previous weeks, and included 33 which were referred to diarrhœa, 18 to whooping-cough, 7 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 3 to measles, and not one either to small-pox or diphtheria; in all, 65 deaths resulted from these principal zymotic diseases, against 64 and 68 in the preceding two weeks. These 65 deaths were equal to an annual rate of 2·6 per 1000, which was 1·7 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had been 16, 24, and 33 in the previous three weeks, further rose last week to 33, of which 10 occurred in Glasgow, 9 in Dundee, and 4 in Paisley. The annual death-rate from diarrhœa in these Scotch towns last week did not, however, average more than 1·4 per 1000, whereas the mean rate from the same cause in the twenty-eight English towns was 2·9. The 18 fatal cases of whooping-cough corresponded with the number in the previous week, and included 17 that occurred in Glasgow. The 7 deaths from scarlet fever corresponded with the number returned in each of the previous two weeks; 5 were returned in Glasgow. Two of the 4 deaths referred to "fever" occurred in Glasgow, and 2 of the 3 fatal cases of measles in Leith. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding five weeks from 93 to 73, further fell last week to 67, and were 15 below the number returned in the corresponding week of last year. The causes of 80, or rather more than 16 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 23·1 and 19·7 per 1000 in the preceding two weeks, rose again to 21·0 in the week ending July 24th. During the first three weeks of the current quarter the death-rate in the city averaged 21·3; while the mean rate during the same period did not exceed 20·7 in London and 18·5 in Edinburgh. The 142 deaths in Dublin last week showed an increase of 9 upon the number in the previous week, and included 12 which were referred to the principal zymotic diseases, against 14 and 11 in the preceding two weeks; 5 resulted from diarrhœa, 4 from "fever," 2 from whooping-cough, 1 from scarlet fever, and not one either from small-pox, measles, or diphtheria. These 12 deaths were equal to an annual rate of 1·8 per 1000, the rates from the same diseases being 6·0 in London and 1·2 in Edinburgh. The 5 deaths attributed to diarrhœa showed a further slight increase upon those returned in recent weeks; but they were below the average for the season. The 4 deaths from "fever" were within one of the number in the previous week. Five inquest cases and 5 deaths from violence were registered; and 46, or nearly one-third of the deaths, were recorded in public institutions. The deaths of infants showed a considerable increase upon the low number in the previous week, while those of elderly persons showed no variation. The causes of 13, or nearly 9 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Joseph John Thompson is granted retired pay, with the honorary rank of Surgeon-General.

ADMIRALTY.—Staff Surgeon William John Rankin, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

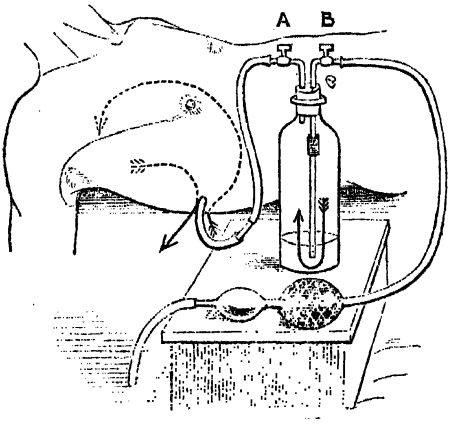
The following appointments have been made:—Staff Surgeon William Brown, to the *Ruby*; Staff Surgeon James D'A. Harvey, to the *President*, additional; and Surgeons A. Gesham (Staff) and H. J. C. Todd, to the *Assistance*, additional, for temporary service with Royal Marines.

RIFLE VOLUNTEERS.—1st West Riding of Yorkshire: Frederick Shann, Gent., to be Acting Surgeon.—2nd Wiltshire: Acting Surgeon C. K. Hitchcock resigns his commission.

THE VOLUNTEER MEDICAL STAFF CORPS.—London Companies: William Wellington Lake, Gent., to be Surgeon.

Correspondence.

"Audi alteram partem."



TREATMENT OF EMPYEMA BY PERFLATION.

To the Editor of THE LANCET.

SIR,—Permit me, through your widely circulated columns, to invite a trial by the profession of a simple method which I have employed with success in the treatment of empyema. My original case being meant for publication at some distant date, I am anxious meanwhile not to delay the wider applications of a treatment which may prove useful to many, and which requires to be tested in a more extensive field than that of my own practice.

Perflation (*Anglice*, "through blast"), as applied in empyema, has the following objects:—(1) the avoidance of all fluid injections, and of the irritation which, as foreign substances, they cannot fail to excite; (2) the evacuation (in the absolute sense) of the pleura, a cavity seldom emptied by fluid injections. The accompanying diagram illustrates the mode of application sufficiently clearly to obviate the necessity for a lengthy description. It should be stated, however, that strict antiseptic precautions and dressings, and the employment of an efficient disinfecting spray are essential parts of the treatment.

The apparatus required is at hand in every hospital, or can be obtained at the shortest notice from any chemist. It

consists of (1) Richardson's bellows; (2) indiarubber tubing; (3) a bottle about 8 in. high, to contain, to the depth of 1½ in., (4) a solution of carbolic acid, 1 in 10; (5) a good cork perforated by two tubes—the one, barely projecting within the bottle, to be connected with the chest, the other of sufficient length to dip not more than ¼ in. below the surface of the solution for connexion with the bellows. Potain's cork here depicted can readily be fitted for the purpose in view, and will be found most convenient; the tap B is superfluous; tap A may be used, as originally suggested to me by Mr. R. F. Benham, whenever it is desired to raise the pressure within the bottle, although in the absence of a tap an ordinary clip or pressure from the fingers will answer as well.

The treatment is applicable at any stage of a suppurating empyema. Where two openings have been made, one is utilised for the entrance of air; the other (lower) opening serves as exit. In such a case reflux of air by the side of the tube inserted into the upper opening must be prevented by a broad flange attached to the tube, or by the firm application around the latter of a moistened pad. It is, however, an advantage of my method that in any ordinary case a second opening is unnecessary. A single good-sized opening will allow sufficient room for the air-supplying tube and also for the escape of the contents of the cavity. Once having grasped the principle of the procedure, each operator will be the best judge of the exact size of the incision required. The tube may be inserted (to a depth of several inches) and perflation begun as soon as the spontaneous flow of pus has ceased, and the same process is to be repeated at each dressing.

The principles underlying the method are the following: 1. Whereas fluids obey gravitation, air will diffuse into every nook and cranny. 2. Whilst an injected fluid stream strikes few spots only, leaving other parts uninfluenced, the current of air will transmit in every direction even fractions of its own pressure. 3. Whilst water merely dilutes fluids and suspends light solids, any fluid or detached solid will sink in air. It follows that if the patient be so placed that the wound strictly coincides with the most dependent spot of the cavity to be drained, any fluid or solid will either escape at the opening or plug it. If a plug be thus formed whilst the bellows are worked continuously, pressure will rise behind the plug and probably expel it. Plugs of this kind are habitually furnished by fragments of necrosed lung, by blood-clots, and by purulent false membranes. I possess evidence of the efficacy of the air-blast in detaching false membranes which had resisted a long course of irrigation; to their presence is probably due the protracted suppuration of many empyemas.

It is unnecessary for me to encroach upon your valuable space with remarks on the merits of the "dry treatment" of suppurating surfaces, or on the surgical value of local ventilation. These topics are reserved for future discussion. I would only add that the favourable results I have obtained in empyema lead me to expect that deep-seated abscesses or suppurating cavities beyond the reach of the finger may, without danger, and with probable benefit, be submitted to the treatment I have sketched. I shall watch for the verdict of surgeons who may be tempted to put the method to a practical test, and I shall be happy to furnish any further explanations to those who may honour me with their inquiries. I remain, Sir, your humble servant,

Curzon-street, Mayfair, July 20th, 1886. WM. EWART.

P.S. The average duration of each perflation has been ten minutes; on one occasion it exceeded three-quarters of an hour. I have not hitherto observed any carboluria, neither has there been the slightest complaint of pain, discomfort, or internal draught. In the intervals between the dressings a stout drainage-tube should provide for the continued patency of the wound, and the opening should be sealed by an air-tight dressing of medicated wool, which will for the time convert the chest into a closed cavity and afford an opportunity for the expansion of the lung.

THE VITALITY OF PATHOGENIC MICRO-ORGANISMS IN WATER.

To the Editor of THE LANCET.

SIR,—Messrs. Crookes, Odling, and Tidy having recently published the results of some experiments which they have made on the vitality of the bacillus anthracis in London water, I should like to offer the following remarks:—

The behaviour of various pathogenic micro-organisms in water has, during the past three years, formed the subject of experiments by several authors, including Koch, Cornil and Babès, Nicati and Rietsch. Within the last two months no less than three papers bearing on this subject have been published, two of them in Germany, by Drs. Wolffhügel and Meade Bolton respectively; whilst the third, by myself, on the "Multiplication of Micro-organisms," was communicated to the Royal Society at their meeting in June last. In this paper I have recorded a large number of experiments made both with the mixtures or organisms found in various natural waters, as well as with three well-characterised forms which are associated with disease—viz., Koch's comma spirillum of Asiatic cholera, Finkler-Prior's comma spirillum of European cholera, and the bacillus pyocyaneus which produces the greenish-blue colouring matter frequently present in abscesses. The methods of research which have been independently selected both by Wolffhügel, Meade Bolton, and myself are identical, and consist in the examination, by gelatine-plate cultivation, of water purposely impregnated with the organisms in question. This method is obviously the one which most recommends itself for the purpose, as it not only enables one to ascertain the presence or absence of the organisms, but also of quantitatively following their multiplication or reduction. I may mention that these three organisms present great differences in their behaviour under similar circumstances; thus the bacillus pyocyaneus is possessed

of far greater vitality in water than either of the other two, its presence being demonstrable even in distilled water after fifty-three days in numbers exceeding manifold those originally introduced. Koch's comma spirillum, on the other hand, was in the purest forms of potable water no longer demonstrable after the ninth day, whilst in London sewage it was found in largely multiplied numbers after twenty-nine days, yet Finkler's spirillum could in no case be detected after the first day, and frequently not even on the day of inoculation. A curious phenomenon, which my experiments, as well as those of Wolffhügel and Meade Bolton, have brought to light, is that when organisms of this kind, which are not the natural inhabitants of the water, are introduced into this medium, a large proportion of them are frequently at first destroyed, a greater or less multiplication in their numbers often subsequently taking place. The bacillus anthracis, as is well known to bacteriologists, appears in two very distinct forms, the bacillus-form and the spore-form, and these present very great differences in their powers of endurance, the former being destroyed with comparative ease, whilst the spores are remarkable for their vitality. Mr. Crookes and his colleagues have apparently experimented with the bacillus-form of anthrax only, which they state is rapidly destroyed when introduced into London water, but Dr. Meade Bolton, who has dealt with anthrax in both its forms, has shown that the spores of anthrax retain their vitality even in distilled water for upwards of ninety days, and that it is only the bacilli which rapidly perish in some kinds of potable water. In polluted well-water, Meade Bolton has also shown that even the bacilli are persistent for upwards of ninety days and the spores for nearly a year, whilst Wolffhügel has found that in polluted river water (the river Panke in Berlin), even when diluted tenfold with distilled water, the anthrax bacilli undergo extensive multiplication.

I am, Sir, faithfully yours,

PERCY F. FRANKLAND,

Normal School of Science, South Kensington Museum, July 26th, 1886.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

To the Editor of THE LANCET.

SIR,—We are authorised to communicate to you for publication the accompanying resolutions, which were passed at a special meeting of the Council of the Medical Officers of Schools Association, held in London on July 22nd.

We remain, Sir, yours faithfully,

WILLIAM S. SAVORY, President.
ALDER SMITH,
CHARLES E. SHELLY, } Hon. Secs., M.O.S.A.

1. "A most important precaution towards the prevention of, and the dealing with, infectious diseases in schools is *undivided medical responsibility*. Therefore the medical officer, and he only, should have the entire school under his daily care and medical supervision. He should have full control regarding the entrance into the school of all boys who are known to have recently had any illness, or to have been exposed to infection, as also over the whole arrangements for isolation, nursing, quarantine, and disinfection." (Page 9.)

2. The medical officer of a public school ought to be appointed by, and should be "responsible only to, the governing body." [Whatever its actual composition in different cases, the governing body is here taken to include the head master of the school.] (Page 9.)

3. It should be the duty of the medical officer to at once report in writing to the responsible authorities the existence of any sanitary defects, and to suggest such remedial measures as appear to him to be necessary. (Page 9.)

4. "A large school should possess a good detached infirmary, to which *all* cases of illness should be sent—no matter in whose 'house' they may occur—and where infectious cases can be thoroughly isolated.....It is of the utmost importance that the infectious wards be *completely* isolated from the rest of the building. And if practicable, there should be a separate building for infectious diseases." (Page 11.)

5. "The first case of infectious disease" which occurs in a school "should be immediately isolated in the infectious ward, and the latter should therefore always be in readiness." (Page 17.)

6. "In the opinion of the Council a serious outbreak of infectious disease in a school affords a sufficient justification for the temporary removal of healthy children by their parents or guardians if they should see fit to do so. Should the outbreak be not only serious in itself—as of typhoid fever or of diphtheria for example,—but dependent upon some sanitary defect which cannot be immediately remedied, or if its origin appear doubtful, then it would be desirable to dismiss the school." (*Vide* Page 21—xxii., 3.)

7. "In any case of serious illness the parents or guardians of the pupil should be at once informed of it. The Council also deem it most desirable that, in replying to inquiries made by parents with respect to any case of serious illness occurring in a school, the precise terms used by the medical officer in describing the nature or the progress of the malady should be communicated either directly by him or through the house master."

8. "The general sanitary arrangements of any school—if not certainly known to be in accord with modern sanitary science—should be thoroughly inspected by a competent person, and all defects at once remedied." (Page 1.)

9. The Council are of opinion that good would result if an official inquiry were instituted into the measures which are taken in our large schools for the prevention of infectious diseases and for the medical care of the pupils.

[1] The quotations in inverted commas are taken from, and the pages refer to, "The Code for the Prevention of Infectious Diseases in Schools," published by the Association in 1885.

THE RECENT CASE OF POISONING BY COMMON SORREL (RUMEX ACETOSA).

To the Editor of THE LANCET.

SIR,—Having made the post-mortem examination on the boy E. Arthur Geary, at the request of Mr. Clarke of Gravelly Hill, who attended him during life, I feel it incumbent upon me to supply you with particulars of the case. Common sorrel is not generally known to be poisonous, and is not mentioned in ordinary text-books on poisons. It is not mentioned by Guy and Ferrier, Blyth, Woodman and Tidy, in Ziemssen's Cyclopædia, or in recent editions of Taylor's work on poisons; but it is mentioned in the first edition of Taylor's work (1847), where a fatal case is mentioned, and reference made to two cases of severe illness following the eating of sorrel recorded in the *London Medical Gazette* (vol. xl., p. 69). Mr. Clarke has supplied me with his notes of the case, which are as follows:—

"I was summoned to see E. Arthur Geary, a boy aged five, at 10 A.M. on June 12th. He had been perfectly well up to the present attack. At once seeing the critical condition of the boy, I desired the presence of their own medical attendant. He not being at home, Mr. Fairley of Aston was sent for, and arrived at about 11 o'clock. The patient was being nursed by a neighbour, and was unconscious, the face cold and pale, forehead moist, extremities cold, respiration slow, pulse frequent and feeble. The prostration was great. There was no convulsion. The conjunctivæ was only slightly sensitive to touch; the pupils small, but not markedly contracted, but later on they dilated. I learned from the father that the patient had been drinking soapy water which had collected in the soap-bowl underneath the perforated dish that held the soap. I also learned from a neighbour that he had been eating a large quantity of the flowering stalks of the common green sorrel (Rumex acetosa) the night before, followed by a meal of plum-cake. He then went to bed, and on the following morning he was seen drinking from the soap-bowl, and in a short time afterwards he fainted. The servant carried him downstairs to his father, who gave him an emetic of salt-and-water, but the emetic had not acted when I saw the boy. I at once placed him on the bed and produced vomiting with a feather, and he ejected about three-quarters of a pint of colourless, odourless, transparent fluid, containing very little mucus, but no blood and no shreds of mucous membrane. I administered a teaspoonful of vinegar, diluted, in order to neutralise the alkalinity of the soap, and gave him an enema of brandy; ordered hot bottles to the limbs and body and a mustard plaster to the heart. He shortly after passed a copious liquid motion, and his pulse was feeble and intermittent. Mr. Fairley now arrived. Upon examining the motion, which was green in colour, we found it to contain a large quantity of stalks, ribbed like the stalks of

sorrel. Small quantities of brandy were administered by the mouth, and brandy was given per rectum; chalk also was administered. At 2 P.M., when I left the patient, there were signs of reaction in the pulse, which was fuller, soft, and 120 per minute. I saw the patient again at 5 P.M.; he was still unconscious and collapsed. Vomiting and purging had been frequent during my absence. He died about 5.30 P.M., seven hours and a half after I first saw him."

The necropsy was performed by myself on June 14th, forty-nine hours after death. Rigor mortis was well marked. There was no trace of external injury. The lips were cyanosed, but there was no erosion or staining. No erosion or staining could be observed on the tongue or mucous membrane of the mouth and throat. The dura mater was tense, but healthy, as were the other membranes of the brain, except that the veins of the pia mater were very turgid. The brain itself was congested, but otherwise perfectly healthy. The stomach was empty, and, except for a small patch of congestion near the pylorus, was healthy. The small intestine contained yellowish fluid material containing stalks of some vegetable partially digested. These stalks were ribbed, and were about the size of sorrel stalks, some of which were 2¼ in. long. The heart was flaccid and empty, otherwise normal. The lungs were a little congested at the base and along the posterior border. The liver and kidneys were congested. The condition of the heart and the visceral congestion observed were compatible with and pointed to death from collapse. Mr. Fairley was of opinion that death was due to the sorrel, the poisonous effect of which was accentuated by the soap-and-water. I expressed agreement with him, but suggested that the vomit, urine, contents of intestine, the soap-and-water, and portions of the viscera should be preserved, Mr. Clarke wisely having secured the vomit and the soapy water. These have been analysed by Dr. Bostock Hill, the county analyst and Professor of Toxicology at Queen's College, who informs me that he cannot detect any oxalic acid or any other poison in any of them. The soap-and-water was a very weak solution of soap, and not at all poisonous.

What was the cause of death in this case? The boy, in perfect health previously, ate a large quantity of sorrel at about 7 P.M.; he was quite well after that, and complained of no pain or nausea, but in the morning he evidently felt ill and thirsty, or he would not have attempted to drink soapy water. He drank about four ounces of the water, and was found a few minutes after on the floor, almost insensible. It appears to me that slow poisoning must have been going on all night, and that the swallowing of fluid was followed by a fresh absorption of the poison, which caused immediate collapse, his getting out of bed also hastening it. Any speculation as to the chemical action between the soap-and-water and the sorrel helps us very little in explaining the collapse immediately following its ingestion, seeing that the soda salt, if formed, is only very slightly more soluble than the potash salt. Mitscherlich estimated that the proportion of binoxalate of potassium present is ·75 per cent. of the fresh plant, and that an ounce of fresh sorrel contains about three grains of that salt. It seems impossible that such a small quantity of binoxalate of potassium—even supposing that the child ate two or three ounces of the plant, which would be a great deal—could prove fatal. It may be that there is some other poisonous substance present not known. The case, in my opinion, was one of death from poisoning by sorrel, and this opinion is confirmed by the fact that a playmate of the boy, who had also eaten sorrel, was very ill for two or three days.

I am, Sir, yours faithfully,

C. W. SUCKLING, M.D. Lond., M.R.C.P.

Birmingham, July 23rd, 1886.

MEDICAL INSPECTION OF PUBLIC SCHOOLS.

To the Editor of THE LANCET.

SIR,—You have from time to time suggested the establishment of some system of medical inspection of our public schools. As a rule, parents know very little of the schools to which they entrust their children. In the case of a boy destined for a public school, he is not a free agent in the matter, but goes wherever his parents choose to send him. The choice is often made in the absence of an intimate knowledge of the institution. The father has been to the same school twenty years before, or some friend's child may have done well there, or the master into whose house the boy is sent may be personally known to the parents, or the boy may have earned a right to go to a particular school by scholarship. Under any of these circumstances the boy passes from parental care into the charge of comparative strangers. He becomes an instrument for the double purpose of supplying a source of income to the house master or the school, and affording a means for the experimental cultivation of whatever intellectual powers he may possess. Vigorous health and intellectualism in the schoolboy should go together. The winner in the race, as a rule, is he who can sustain the longest effort. Our lunatic asylums, our prisons, and our factories are subjected to regular inspection over and above that given by the local officers, and some similar regular inspection of all public and private schools should take place. It would be unreasonable to expect that a body of such highly intellectual men as the "house masters" at our public schools should yield to the solitary authority of their medical attendant in matters of sanitation. They know full well that experience limited to the sanitation of a public school is very inadequate. Nor would it be reasonable to expect the governing body of a public school to give an authority to the medical attendant—often a very young man—which might clash with that of the head or house master's. The house masters are, as a rule, only subordinate to the head master and governing authority in matters of education. The house masters are, in fact, proprietors of private boarding-houses, limiting their boarders to boys educated at the school in which they teach, and, like householders in general, are very sensitive on points of sanitation. If every public and private school were required to be registered, a system of regular inspection might be instituted. This should be by medical officers appointed by the Government. The authority thus instituted would be independent of the governing body and the masters, and would effect a much-needed improvement in the sanitary and medical arrangements of our public and private schools.

It appears to be very commonly lost sight of that masters of boarding-houses at our public schools are at liberty to choose their own medical attendant, and that it is not within the power either of the governors or the head master to interfere with their rights. For more than twenty years I had charge of an average of 400 public school boys, and have therefore had some insight into the subject, or I would not venture to trespass on your space.

I remain, Sir, yours obediently,

July 28th, 1886. A GENERAL PRACTITIONER.

THE "HOMES" OF THE WINDSOR POOR.

To the Editor of THE LANCET.

SIR,—The good hope there was here in March last that the Windsor poor were about to be delivered from their slums, and were at last to be offered "human homes," is, I fear, sick unto death. I will give you the facts, and you and your readers can then diagnose the case for yourselves.

George IV., William IV., the late Prince Consort, and Queen Victoria have successively been interested in bringing about the demolition of Windsor's slums, and yet these moral plague-spots remain—some of the worst and most openly convicted of them—unto this day, not only a local scandal, but, as notorious to all men, a public disgrace. THE LANCET has vigorously arraigned them; indeed, every newspaper outside the Royal borough, beginning with *The Times*, has delivered itself against the notorious reproach of Windsor. In March last a meeting was convened at the Town Hall here, with the Mayor in the chair, to devise a way out of the evil, and thus to lay the scandal. At this meeting, at which I was present, Mr. Richardson Gardner, M.P., explained the provisions of a scheme for the better housing of the poor in the Bier-lane district. In regard to this scheme, it was announced that three of the Royal Princes had very readily consented to act as patrons. The further consideration of this scheme was adjourned for a month, that it might be seen how far the Corporation of Windsor would, in that period, elect to go in aid of its development. An influential member of the Town Council—none other, indeed, than the ex-Mayor—subsequently did move for a Town Improvements Committee, and the motion of Mr. Oberlin Harris was agreed to. The immediate aim of this committee was to facilitate the making of roads through dark and forbidding districts, needing, physically and morally, to be thus opened up. From that day to this I have seen

nothing and heard nothing of Mr. Richardson Gardner's cheme. Whether it be alive or whether it be dead nobody eems to know. I do not say this to reproach Mr. Richardson Gardner, for I believe he is now anxiously resolved to do his utmost to abolish the moral cesspools of Windsor. So ar as has come within my knowledge, he does not at present possess a house in the Royal borough that is not a human nome. I have also every reason to believe that a majority of the Corporation are only too ready to help to put an end o this odious scandal. We have thus the Royal Family, the borough member, a well-informed majority of the Corporation, and a unanimous outside public opinion seeking to rid Windsor of the taint and reproach of its slums—slums that are as angry sores suppurating in the busy life of its chief street, socially and morally, consigning to a living death the dwellers amongst these tombs; and yet this rank barbarism promises to outlive the fiftieth year of the beneficent reign of such a queen as Queen Victoria. Whether it be that the public spirit which in March last seemed able to carry all before it is puling and palsied; whether it were only a spasmodic seizure which has been succeeded by total paralysis; or whether the mountain was, peradventure, in labour, not even with the proverbial result, for it has not had the strength to bring forth, I cannot tell. Perhaps THE LANCET can. Yours faithfully,

ARTHUR ROBINS, M.A.,
Rector of Holy Trinity, Windsor; Chaplain to the Queen, the Prince of Wales, and H.M.'s Household Troops.

Holy Trinity Rectory, Windsor, July, 1886.

THE PREVENTIVE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—My object in publishing the case of Mr. A. B. C. was to afford a contrast to the ordinary treatment of early syphilis, which I believe to be opposed to the best interests of the patients, and which might be described as follows:—A surgeon, upon seeing a patient with a primary chancre, is frequently perplexed—especially if he lack much experience in the diagnosis of syphilis, or if the lesion be immature and its physical characters not strongly pronounced—as to the recognition of the disease before him. Only too often the advice given is to wait until the diagnosis is concluded satisfactorily by the appearance of secondary symptoms before resorting to specific treatment. A sore-throat and corona veneris having appeared in due course, the patient is now informed that he certainly *is* the subject of syphilis, and that its virus really *was* implanted some weeks previously—that is, just before he applied for treatment. An eighteen months' or two years' course of mercurial treatment is now rigorously prescribed, and the subject of the experimental diagnosis comforted by being told that the delay consequent thereon has not materially retarded or furnished his prospect of a cure (in about two years' time). Surely a consideration of the pathogenesis of syphilis shows that the converse is the right line of practice. Every reasonable practitioner knows very well that the *earlier* the treatment of syphilis is commenced, so much the better is the prognosis, and that therefore to withhold specific remedies for the sake of establishing scientific observations is equivalent to conducting an experiment highly detrimental to the patient.

Making full allowance for the conflicting evidence which still envelops the theory of the absorption of the virus, I incline to the view that the system is not perfectly invaded by the poison before the maturation of the chancre, and that a thorough destruction of it, whilst immature, will modify, if not arrest, specific contamination. In the case of Mr. A. B. C., I was morally convinced from the history, coupled with the physical condition presented, that I had destroyed an immature chancre, and Sir William Jenner, who saw the patient with me, accepted this view as correct. Drs. Harries, Johnston, and Craig (who did *not* see the patient) think otherwise. But the idea of withholding specific treatment never occurred to Sir William Jenner or myself, and I am quite sure Mr. A. B. C. would not have desired that course in order that an opportunity for the appearance of secondary phenomena might have been afforded to establish the diagnosis to the satisfaction of anyone who might be sceptical upon the subject. Permit me to repeat that the destruction of a primary chancre with Paquelin's cautery, the growth being previously painted with a solution of cocaine, is a very trifling surgical procedure; and I should think that to excise the infected lymphatic glands also would, in some cases, be a most rational mode of treatment. The criticisms offered by the gentlemen referred to, although very interesting, have little bearing upon the point at issue. It seemed to me that the publication of a solitary case might possibly prove of benefit to the profession and community, as being descriptive of a simple plan which could be tested without delay by any practitioner who might incline to imitate the practice.

I am, Sir, yours faithfully,

CHAS. E. JENNINGS.

Park-street, Grosvenor-square, W., July 28th, 1886.

"THRUST WOUNDS THROUGH THE ORBIT."

To the Editor of THE LANCET.

SIR,—In the special article on "Thrust Wounds through the Orbit" in last week's LANCET, I notice that no reference is made to the possibility of death occurring from a wound through the orbit of the internal carotid artery, where it curves round the side of the body of the sphenoid bone immediately behind the optic foramen. Curiously enough also, I have not been able to find any mention of this accident in any of the well-known works on ophthalmic or general surgery, nor in the article on "Injuries of the Orbit" in "Heath's Dictionary of Surgery." The only two cases of the kind which I can find recorded are one by Nélaton, which is referred to by Mr. Treves in his excellent work on "Surgical Applied Anatomy," and one which I published myself some years ago, and which is quoted in Dr. Neale's "Medical Digest." In this instance, during a quarrel a man received a thrust in the eye from an umbrella, blood flowed copiously from the wound, and the man was immediately taken to the Gloucester Infirmary, which is distant not more than about four minutes' walk from the place where the accident happened. I saw him directly after his admission, but he was then dead. His face and clothes were covered with blood, but after wiping this away and making a careful examination of the head, face, and neck, and body generally, no wound could be discovered which would account for such copious bleeding, nor, in fact, was there any external evidence to show what was the cause of death. There was a slight laceration of the conjunctiva on the inner side of the left eye, but no wound of the eye itself, nor of the skin of the eyelids. With the exception of the injury to the conjunctiva, there was no wound to be found on any part of the body. By direction of the coroner a post-mortem examination was made, and a careful dissection of the orbit showed a wound of the internal carotid artery at the bend which the vessel makes just behind the optic foramen; the optic nerve was divided, and a piece of the brass ferrule of the umbrella was found lying loose in the tissues at the back of the orbit. There was no wound of the eyeball itself, nor any injury to the brain or inner wall of the orbit, but there was a fracture through the lesser wing of the sphenoid.

The puzzling feature of this case was the enormous quantity of blood which had, from the account of the bystanders and the appearance of the clothes of the patient, evidently been lost, without there being any external wound apparently sufficient to account for it. This rare accident is, I think, of sufficient anatomical and surgical interest to warrant publication of this note of it, as supplementary to the interesting cases in your special article of last week.

I am, Sir, yours faithfully,

ERNEST D. BOWER,

July 20th, 1886. Ophthal. Surgeon, Gloucester Gen. Infirm.

ADELAIDE JUBILEE INTERNATIONAL EXHIBITION.—Advance copies of the regulations for next year's South Australian Exhibition, to be opened in Adelaide on June 20th, 1887, have been issued. The age of the colony being coeval with the reign of Her Majesty, the title "Jubilee Exhibition" indicates in a double sense the design of its promoters. The exhibits are divided into seven departments and over 700 classes. Seven classes are devoted to medicine and surgery, six to vegetable products used as food, and seven to chemical manufactures. The Exhibition promises to prove a most interesting one, and it is to be hoped that it will meet with the support, both at home and abroad, which it undoubtedly deserves.

MANCHESTER.

(From our own Correspondent.)

THE ROYAL INFIRMARY.

THE annual report of the Royal Infirmary, to be presented to the trustees on the 29th, has just been issued, and gives particulars of the year's work of the parent institution and its allied branches. The total number of patients under treatment at the infirmary, the Cheadle Convalescent Hospital, and the Fever Hospital has been 33,895, an increase of about 3000 on the previous year, due to greater numbers of out and home patients; the in-patients at each place having been less than the previous year. The Board attribute this increase to the abolition of recommendations in the admission to treatment of the out and home patients. The total expenditure has been at the infirmary £17,010; the in-patients here numbered 4414. The expenditure at the Convalescent Hospital has been £5360 for a total of 1345 patients, averaging £4 as the total cost per patient, as against £2 18s. in the previous year. At the Fever Hospital 841 patients have been admitted, and the expenditure has reached £5943, averaging something over £7 per patient, as compared with £5 9s. in the preceding year. At the latter hospital considerable additions have been made to the buildings, two new blocks have been erected capable of accommodating seventy-two patients, and a new building has been erected for the nursing staff capable of holding fifty nurses, though it is to be hoped that Manchester is not going to have an outbreak of epidemic disease necessitating the employment of fifty nurses at one hospital.

ANCOATS HOSPITAL.

On the 21st inst. the annual meeting of the Ancoats Hospital was held. This charity is steadily making progress in the face of much difficulty, and its occupied beds increase yearly in number. Much of its success is due to the untiring interest of its hon. secretary, Mr. Alexander Forrest.

BRITISH MEDICAL ASSOCIATION.

The arrangements for the meeting of the British Association in this city next year are now well in hand. A most influential local committee has been formed, and a guarantee fund not to exceed £10,000 in now being raised. The little difficulties which arose in the first instance are all smoothed down, and at a meeting held yesterday, the mayor, Mr. Alderman Goldschmidt, was appointed chairman of the General Committee and Mr. Alderman Thompson chairman of the Executive Committee.

PROPOSED INDUSTRIAL EXHIBITION.

Next year promises to be a red-letter one for Cottonopolis, as a scheme is now in progress for holding a large industrial exhibition, £80,000 having already been promised towards a guarantee fund for the same; and a still more important undertaking, it is hoped, will be commenced—viz., the ship canal, if the temporary check it has sustained is satisfactorily overcome.

VICTORIA UNIVERSITY.

Numerous applications have been made to this university for courses of lectures to be delivered on the plan of the Cambridge courses. At present no definite scheme has been drawn up by the Victoria University, but the authorities will, as far as feasible, arrange for a number to be given during the coming winter, as a continuation of those commenced last year in various districts.

STRYCHNIA POISONING.

An unusual case of poisoning by strychnine has occupied much attention during the present assizes. A woman at Ashton, by means of "mice poison," has poisoned her husband, her daughter, and a neighbour's wife. The evidence, which was chiefly circumstantial, left no doubt as to her guilt, and she is now lying under sentence of death. Two of the bodies were exhumed; these both showed rigor mortis some weeks after burial; arsenic was proved to be present, but no strychnia. In the third case (the one for which she was actually tried) both substances were found, and physiological confirmation was obtained by the action of the strychnine on frogs and mice.

Manchester, July 27th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE HOSPITAL SUNDAY FUND.

AT a late meeting of the committee of the Hospital Sunday Fund it was mentioned that the total amount collected here since the commencement of the movement had reached £51,200, and that it was a fitting time to recognise the services of their hon. secretary, Mr. R. Henry Holmes, and to signify to him in some way their approbation of his indefatigable labours. Mr. Holmes, it was stated, was most reluctant to accept any testimonial; but ultimately it was agreed to present Mrs. Holmes with a portrait of her husband, and each member of the committee to be also provided with a large cabinet-sized photograph. Never was a recognition of this nature better earned or deserved, Mr. Holmes being at once the originator, and to some extent the life, of the movement, for the interest he has shown at the commencement has never flagged.

"A PLEA FOR THE DOCTORS."

A kind-hearted writer in the *Newcastle Weekly Chronicle* says that "a few weeks ago there was an announcement in some of the papers that a lady of Liverpool, Mrs. Charles Furner, had assigned to trustees the sum of £20,000 for a fund for retired Liverpool clergymen, to allow them £200 a year. All honour to the lady for her munificent gift and loving care for the clergymen, but there is another class of men who need similar help in their declining years—I mean the doctors, some of whom have borne the heat and burden of the day for twenty or thirty years; liable to be called out at any hour of the night; sometimes paid, more often not; striving always to pay their own debts (for they are honourable men as a rule), yet at times scarcely knowing how to do so through lack of honour amongst some of their patients. Often weary in body and overtaxed in mind, what wonder that they often break down at the age of sixty, while many men at that age are still fresh and vigorous. The writer personally knows such a case, one who at sixty-five is, through severe illness, thoroughly broken down in health, and will not be able to work much in future, yet with next to nothing to fall back upon. Always tender-hearted and generous in the past, never refusing help to others in time of need, upright and honourable in all his transactions, he is now weak and ill, and over-burdened with care about the future. What an estimable boon would a pension like Mrs. Furner's be to such a man! It would relieve him of corroding care, and make his last days serenely happy."

SANITARY MATTERS AT WHITBY.

Dr. Herbert reports of this favourite northern health resort that there is now an entire absence of zymotic diseases in the district, and that the town was never in a more healthy condition. The 100th annual meeting of the Whitby Public Dispensary has just been held, when it was stated that 975 cases had been treated during the year, and of these 892 had been discharged cured or relieved. Dr. Tinley was appointed at the same meeting one of the hon. physicians of the institution.

NARROW ESCAPE OF A SURGEON.

An accident occurred at Wallsend on Saturday last, whereby Dr. Frederick Mears, of Gateshead, nearly lost his life. He was riding to Tynemouth to attend a muster of the Volunteer Corps. At Walker Gate his horse took fright at a passing train, and dashed along the turnpike road at a furious rate. The rider lost control over the animal, and great consternation prevailed at Wallsend when the horse and rider galloped through the whole length of the crowded High-street. When opposite the Café, the horse dashed with great force against a lamp-post, and fell dead on the spot. Dr. Mears escaped with a rather severe shaking and some slight contusions. He never lost his presence of mind, but kept shouting to the crowd to clear the way as the animal galloped furiously along the street.

Newcastle-on-Tyne, July 26th.

THE Grand Cross of Isabel the Catholic has been conferred upon Señor Don Estéban Sanchez Ocaña, body physician to the Queen of Spain.

EDINBURGH.

(From our own Correspondent.)

CLOSE OF THE SUMMER SESSION.

THE classes held during the summer session in the University and Extra-mural Medical Schools closed last week, and the great bulk of student life has vanished from the city for a season. Professional examinations, however, are detaining both teachers and candidates for a time in town; the final examinations at the University and at the Colleges are just completed, and the first and second intermediate examination at the former are at present in progress. The results of the final examination at the University have been very satisfactory this year; the standard of ability has proved to be a high one, of 280 candidates more than 220 having passed, who will proceed to the degrees of M.B. and C.M. at the annual graduation ceremonial next week. In both the intermediate examinations the proportion of rejections is very much larger than in this, but as the returns from these are not yet complete, it is impossible to compare the ratio of proportionate success in each. Excluding in each case candidates who do not appear for the first time at the several examinations, I believe the proportion of successful candidates will be approximately in the first one quarter, in the second one half, and in the final examination three-quarters, of the total number of competitors.

A NEW MEDICAL SOCIETY.

Under the name of the Edinburgh Pathological Club a new society for the discussion of medical topics has been inaugurated. I understand that its constitution is based on the principle which has produced such admirable results in the case of the Pathological Society of Glasgow, which meets at short intervals under the presidency of Prof. Gairdner. The membership is to be closely circumscribed as regards numbers, and whilst the term "pathological" in its title is to be interpreted in a comprehensive sense, the topics introduced are to be exclusively such as are capable of discussion on a basis of experimental science. The new Club will meet monthly during the winter session.

EXPERIMENTAL WORK IN EDINBURGH.

Since my reference three weeks ago to the state of preparedness for experimental work afforded by the completion of the University laboratories, an appointment has been made which shows that this fact is now generally recognised, and along with it the equally important matter that Edinburgh can produce workers ready to make good use of these opportunities. The Grocers' Company of London have awarded one of their Triennial Research Scholarships to Dr. G. Sims Woodhead, to enable him to prosecute researches in morbid anatomy and pathology. In accepting this appointment, Dr. Woodhead resigns the post of Senior Demonstrator of Pathology under Professor Greenfield, which he has occupied for several years with great acceptance, and the laborious duties of which he has discharged with indefatigable energy. He has already shown power as an author and investigator, and now that he is relieved from the strain of several hours' routine teaching daily, his merits in these respects will come yet more into prominence, as his whole energies will be now diverted into the more profitable channels of experimental research. In addition to his present appointment, Dr. Woodhead holds that of Joint Pathologist to the Infirmary (with Dr. Bruce), which gives him the control of most extensive supplies of material suitable to the purposes of the scholarship.

HONOUR TO AN EDINBURGH DOCTOR.

Dr. Arthur Mitchell, LL.D., one of Her Majesty's Commissioners in Lunacy, has been gazetted as a Companion of the Order of the Bath, Civil Division. Dr. Mitchell is well known, apart from his special eminence in mental science, as a distinguished antiquarian, and holds the post of Professor of Ancient History to the Royal Scottish Academy.

Edinburgh, July 28th.

MEDICAL MAGISTRATE. — The name of Andrew Marshall, M.D., appears in a list of gentlemen who have just been placed on the Commission of the Peace for the borough of Preston.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

THE extensive additions to this University commenced about two years since will very soon be completed, and when handed over to the authorities of the university the building may be regarded as one of the most complete and efficient of its kind. The anatomical room is 120 ft. long by 30 ft. wide, and the preparation room attached is complete in every respect, several new features in this department having been introduced. The physical laboratory is 90 ft. by 30 ft., while the physiology department adjoining is 87 ft. by 30 ft. wide, the roof being of pitch pine varnished. The chemical laboratory is well equipped, and close to it is a hall 58 ft. by 16 ft. wide for the study of histology. The lavatories are considered perfect, and in connexion with them is a smoking-room 60 ft. by 30 ft. A new feature is a rarefying shaft running from the weather course over the brickwork to the top 85 ft. high, which is intended to remove the fumes from the students' working benches. The tower attached is an imposing structure, and is 120 ft. in height. At a meeting of Convocation, held this week, among the business transacted was that of electing two representatives in the Senate of the University for the ensuing three years. There were four candidates nominated—viz., Messrs. Arthur Hill Curtis, James J. Shaw, M. J. Farrelly, and T. P. O'Connor, M.P. The two first-named gentlemen were elected, the voting being as follows:—Mr. Curtis 348, Mr. Shaw 315, Mr. Farrelly 226, Mr. O'Connor 161.

BOARD OF SUPERINTENDENCE OF DUBLIN HOSPITALS.

The twenty-eighth annual report of the Board of Superintendence of the Dublin Hospitals which receive aid from Parliament has recently been issued. There are nine hospitals, which have a sum of nearly £16,000 distributed among them; and of these institutions three are general hospitals, two midwifery, one ophthalmic, one fever, and one special hospital for the treatment of venereal diseases. The patients treated in these institutions for the year ending March last numbered 9503, and of these 443 died, or a mortality of 5·29 per cent. on those cases treated to a termination. Of the three general hospitals, the mortality on the cases treated to a termination was lowest in the Richmond, which result reflects great credit on the medical staff and managers of that institution, more especially as the building is one which has many defects in its construction and arrangements. Contrasting next the two midwifery institutions, as regards the mortality of patients admitted and the expenditure, there is a considerable difference which is worth noting. The Rotundo Lying-in Hospital had a mortality among the labour cases of only ·58 per cent., as compared with a death-rate of 2·63 per cent. in the Coombe Hospital. The average annual cost per bed for maintenance and for establishment in the Rotundo Hospital was £50 12*s.* 4¾*d.*, and in the Coombe Hospital £65 0*s.* 5¾*d.*, or a difference per bed of £14 8*s.* 1*d.* between institutions admitting the same class of cases. It may here be remarked that of the hospitals receiving a Parliamentary grant the most economically worked in these particulars is the Hospital for Incurables (£26 12*s.* 4¾*d.*), and the highest the Cork-street Fever Hospital (£79 19*s.* 3½*d.*)

CORK-STREET FEVER HOSPITAL.

It appears from the report for the past year, ending March last, that the decrease in the number of patients admitted, as compared with the previous two years, was due to the diminished prevalence during the year of typhus fever, scarlatina, measles, and pneumonia. The only cases of small-pox were imported from England, and every precaution was taken in the hospital, when a case was admitted, to prevent the spread of contagion. I am informed that two of the visiting medical staff are paid out of the funds of the hospital—a circumstance which, if correct, would appear to call for some alteration.

THE SPIDDAL TRAGEDY.

Mr. Terence B. Brodie, medical officer of Spiddal Dispensary, situated about eight miles from Galway, who recently shot his wife dead, was last week, before the Lord Chief Baron, found incapable of pleading, medical evidence showing that

he is suffering from alcoholic insanity. He had for some time been addicted to stimulants, and had an attack of delirium tremens previously to the sad occurrence.

THE LATE DR. EAMES OF CORK.

The remains of this much-lamented member of the profession were interred in the New Cemetery last week, the funeral being attended by some of the most influential citizens. The members of the medical profession present walked in front of the coffin, which was covered with wreaths, one of which was sent by H.R.H. the Duke of Cambridge.

LUNATIC ASYLUM APPOINTMENTS.

By the retirement of Dr. Lalor, who has held the post of resident medical superintendent of the Richmond Lunatic Asylum, Dublin, for so many years, a vacancy has arisen, which has been filled up by the appointment of Dr. Conolly Norman, the medical superintendent of Monaghan Asylum. The late Dr. Eames, of the Cork Lunatic Asylum, has been succeeded by Dr. Jameson Dwyer, of Mullingar Lunatic Asylum.

In consequence of the overcrowded state of Santry churchyard, a sworn inquiry was held last week as regards its sanitary condition, and as a result of the evidence tendered it will be closed against any further interments.

Dr. Charles E. Ryan, of Emly House, Tipperary, has been placed on the Commission of the Peace for co. Tipperary.

Dublin, July 27th.

PARIS.

(From our own Correspondent.)

THE TREATMENT OF RABIES WITH HOANG-NAN.

ACCORDING to the *Gazette Médicale de Nantes*, twenty-four cases of rabies have been treated with Hoang-nan by Dr. Barthélemy and several other medical men of that city or of the department. The first case so treated was in the month of March, 1882, the last in April, 1885. Ten times, at least, the bites, which were most frequently multiple, were situated on the hands, once on the hand and on the face. In the majority of cases cauterisation was completely omitted, or practised several hours or even several days after, with agents little active, such as liquid ammonia or a solution of carbolic acid. Two of the patients, who were closely observed by Dr. Barthélemy,—viz., a man of thirty and a lad of sixteen—presented symptoms of rabic mania: persistent insomnia, anxiety, nocturnal agitation, the desire to run, hallucinations, barking, &c. However, none of these persons felt hydrophobic, nor have any of them, to this date, succumbed. The duration of this preventive treatment was, on an average, twelve days. The total dose of the powder of hoang-nan ingested during this time, varied in adults from six to eight grammes. It was scarcely necessary to go beyond one gramme per day to obtain the physiological effects of the medicine—exaggeration of the reflexes, cramps, rigidity, slight trismus. The maximum dose was arrived at progressively, and in some cases the treatment was terminated by gradually decreasing doses. From the above cases the author deduces either that rabies is communicated much more rarely to the human species than is generally admitted, or that the hoang-nan, administered progressively to the physiological effects *during the period of incubation*, sufficiently and efficaciously modifies the nervous system and the entire economy to prevent the evolution of the rabic virus.

M. PASTEUR.

Another victim to hydrophobia, after having been submitted to M. Pasteur's anti-rabic treatment, has been reported. The subject was a young girl of eleven years of age, who was bitten at Chassagne, in the department of the Jura, on April 27th last. She was taken to M. Pasteur's laboratory nine days after. During the fifteen days she remained in Paris she went through the usual inoculations, with ten bouillons of progressive strength; after which she was declared cured and sent back to her family. On June 13th the girl presented the first symptoms of hydrophobia and refused all nourishment. She afterwards presented in succession all the other symptoms, and died on June 17th in a fit of extreme violence. And still another patient of M. Pasteur's is reported to have just died. The patient was a Russian woman, who was bitten by a wolf, and, after having undergone the usual inoculations at the laboratory, returned to her home, where she soon after succumbed to hydrophobia. This death is the fourteenth out of fifty-four persons bitten by wolves, which would give an average mortality of 26 per cent., which is about the average given in recent statistics of deaths from the bites of wolves. Intelligence has just been received from St. Petersburg to the following effect:—On the 3rd and 4th of May last, seven persons (five children and two women) were bitten by a mad dog in the district. They were immediately sent to Paris under the care of Dr. Winow, to be treated according to Pasteur's method. Of the seven patients, three have died since their return to Russia. Dr. Ferreira dos Santos, Professor at the Faculty of Medicine of Rio de Janeiro, and Director of the Hospital of Santa-Casa, has been commissioned by the Emperor of Brazil to proceed to Paris to study M. Pasteur's anti-rabic method with a view of establishing a similar institution in that country. Dr. Ferreira dos Santos is charged to hand to M. Pasteur, with a letter from the Emperor, the Grand Cross of the Order of the Rose.

THE NIGHT SUPPLY OF DRUGS.

As a complement to the night medical service established some time since in Paris, and which has been found very useful, the Municipal Council has decided on creating a night service for the supply of drugs. A list of pharmaciens, who have volunteered for such service, is posted up at the different police-stations, where patients may apply for medical aid, and the medicine, prescribed by a doctor told off for the purpose, may be obtained gratis from a pharmacien on the list, but those who are able to pay will be charged cost price, and one franc and a half extra for the trouble of being attended to at night.

RETIREMENT OF PROFESSORS.

M. Gavarret, Professor of Medical Physics, M. Hardy, Professor of Clinical Medicine, and M. Sappey, Professor of Anatomy at the Faculty of Medicine, Paris, having reached the limit of age, have been placed on the retired list.

Paris, July 28th.

ROYAL COLLEGE OF PHYSICIANS.

AT the ordinary meeting of the Fellows of the Royal College of Physicians, held on the 29th inst., the President, Sir W. Jenner, Bart., in the chair, four gentlemen were admitted to the membership of the College, and the licence was granted to seventy-seven candidates who had been successful at the recent examination.

A communication was read from the Society of Apothecaries asking the College to consider the advisability of allowing the Society to combine with the two Colleges for examination purposes, and pointing out that if this step were not taken, the Society would, under the new Medical Act, be enabled to nominate assistant examiners and confer a statutory diploma; that the Colleges of Physicians and Surgeons would thereby be exposed to very serious competition. A similar letter has been addressed to the Royal College of Surgeons. The consideration of the subject was referred to a special committee to be nominated by the Presidents of the two Colleges.

The College seal was affixed to a deed of agreement between the two Colleges in respect to their conjoined undertakings.

The quarterly report of the Finance Committee and the annual reports of the Library Committee and of the Curators of the Museum were read and adopted.

On the recommendation of the Committee of Management, it was resolved to accept certificates of attendance upon the classes of chemistry, physiology, and anatomy at the University of Adelaide from candidates for the diplomas.

The election of Censors and College officers then took place, the list being as follows:—

Censors: Drs. Handfield Jones, Bristowe, W. H. Dickinson, and James Andrew. Treasurer: Sir Dyce Duckworth. Registrar: Sir Henry Pitman. Harveian Librarian: Dr. Munk. Assistant Registrar: Dr. Edward Liveing. Curators of the Museum: Drs. Wegg, Beale, Bastian, and Curnow. Finance Committee: Dr. Hare, Dr. Wm. Wood, and Sir Edw.

Sieveking. Examiners in Chemistry and Chemical Physics: Drs. Thomas Stevenson, Bernays, W. J. Russell, A. Dupré, and William Foster, F.C.S. Examiners in Materia Medica, Medical Botany, and Pharmacy: Drs. Mitchell Bruce, Frederick Taylor, Murrell, Tirard, and D. B. Lees. Examiners in Elementary Physiology: Drs. William Ewart and V. D. Harris. Examiners in Physiology: Drs. Allchin, Wooldridge, and Professor Schäfer. Examiners in Osteology and Anatomy: Dr. James Anderson and Mr. Henry Morris. Examiners in Medical Anatomy and Principles and Practice of Medicine: Drs. Beale, W. H. Stone, Sturges, Sutton, Cheadle, Pye-Smith, Whipham, Bastian, Cayley, and Sir Dyce Duckworth. Examiners in Midwifery and Diseases peculiar to Women: Drs. Priestley, Gervis, Galabin, and Watt Black. Examiners in Surgical Anatomy and Principles and Practice of Surgery: Messrs. George Pollock, Morrant Baker, Marcus Beck, and Sir William MacCormac. Examiners in Hygiene: Drs. Thomas Stevenson, Corfield, Ballard, and Thorne Thorne.

A vote of thanks to Dr. Allchin for his services as assistant registrar during the past three years was unanimously passed, on the motion of Sir Dyce Duckworth, seconded by Sir Henry Pitman.

Obituary.

JOHN ARTHUR POWER, M.A. CANTAB., M.R.C.P.L.

THE death of John Arthur Power, which took place suddenly at his residence at Bedford on June 9th last, removes a man who in his particular line was as well known and successful as any man in the profession. For some forty years, at first by himself, afterwards in conjuction with his brother, Wm. Henry Power, and again, since his brother's death, by himself, Mr. Power carried on the tutorial classes which have made his name familiar to hundreds of members of the medical profession; in fact, there is hardly a corner of the globe frequented by Englishmen in which former members of the Power classes are not to be found. The deceased gentleman's grandfather, Dr. John Power, was a medical practitioner of repute at Lichfield. His father, also Dr. John Power, was a physician and obstetrician of considerable repute—an acute observer still referred to as an authority.

John Arthur Power was educated at Merchant Taylors School, whence he proceeded with a scholarship to Clare College (then Clare Hall), Cambridge. Here he took his B.A. degree in 1832, being bracketed 9th wrangler and placed at the top of the third class in classics. Among those who graduated the same year were Dr. Cookson, the late master of Peterhouse, Dr. Thompson, the present master of Trinity, the late Dean Alford of Canterbury, Bishop Harold Browne of Ely and Winchester, Thos. Webster, of patent law celebrity, Robt. Potts, the editor of Euclid, and Shillito, the consummate Greek scholar. Power afterwards proceeded to the degrees of M.A. and L.M., and became senior Fellow of his college. Later on he became M.R.C.P.L. Several other members of his family at or about the same time held university honours at Cambridge. An uncle, the Rev. Joseph Power, 10th wrangler (1821), became Fellow of Trinity Hall, Fellow of Clare, and University librarian. Another uncle, Sir Alfred Power, K.C.B., late Vice-President of the Local Government Board in Ireland, was Fellow and is now honorary Fellow of Downing; while a cousin, the Rev. John Power, 8th wrangler in 1841, was Fellow and tutor and subsequently master of Pembroke College.

The deceased gentleman was a man of very considerable scientific attainments, with a great aptitude for imparting information. He was an accomplished botanist, zoologist, and one of the most prominent of English entomologists. In this branch of natural history he was an acknowledged authority, and his collection of British coleoptera is one of the most complete in existence. Though never in active general practice, he was frequently called in consultation by his old pupils, and kept fully abreast of the times in medical knowledge; in fact, he was generally in advance of them. Long before the anti-zymotic treatment of disease—now almost universally accepted by the profession—was known Dr. Power had enunciated the theory, and in conjunction with his life-long friend and pupil, Dr. Wilkinson of Sydenham, had proved its accuracy by practice. He was also—until incapacitated for all active work by a severe stroke of paralysis in January, 1882—for many years medical officer to the Sovereign Insurance Office. He was notably a kind-hearted man, a genial companion, a good friend, and had in a high degree the power of attracting the confidence and affection of those with whom he was brought in contact. He leaves a widow, two sons, and six daughters.

MR. FRANCIS SLAUGHTER ROGERS, M.R.C.S., L.A.C.

ON Sunday, the 18th inst., after a lengthened period of ill-health, which had compelled his retirement from practice some seven years ago, died Mr. Francis Slaughter Rogers, of Westmeon, Petersfield, Hants, within a few weeks of the completion of his seventy-fifth year. Mr. Rogers was the seventh child of the late George Vining Rogers, who practised in the same village for upwards of forty years, and who, solely from the resources of such practice, brought up and sent out into the world thirteen sons and three daughters, one being Professor Thorold Rogers, late M.P. for Bermondsey, and another, Dr. Joseph Rogers of London, of sanitary and Poor-law celebrity.

Mr. F. Rogers was educated at the Webb-street School of Medicine by the Brothers Grainger and the late Dr. Robert Lee. In his day he had the run of the conjoint hospitals of Guy's and St. Thomas, an opportunity he turned to good account. He joined his father's practice in 1835, and in 1841 succeeded to the whole of it. He was far above the average of provincial general practitioners; a bold and skilful operator, and of rare judgment in the diagnosis of disease. He therefore merited and retained the confidence of a large circle of patients and friends. By the retirement of Mr. Francis Rogers from practice the connexion of the family with Westmeon, which had lasted unbroken for over a hundred years, came to an end, his grandfather, father, and himself having continuously resided in Westmeon or its vicinity for the whole of that lengthened period.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on July 22nd:

Baker, William Henry, Clapham.
Crossley, Ely Wilkinson, L.R.C.P.L., Greetland, Yorks.
Gilkes, Ernest Osmond, L.R.C.P.L., Dulwich.
Harger, Frank Arnold, Barnes.
Haynes, Edward James Ambrose, L.R.C.P.L., Greenwich.
Hutcheson, James, L.R.C.P. Lond., Edinburgh.
Lewis, Percy George, L.S.A., Lincoln's-inn-fields.
Percival, Archibald Stanley, Woking.
Permewan, William, Redruth.

Admitted on the 23rd inst.:

Bahadhurji, Kaikosro Nasarvanji, West Norwood.
Barclay, Wilfred Martin, Clifton, Bristol.
Blancard, Joinville Toby, L.R.C.P.L., Middleton-square.
Blaxland, Ernest Gregory, L.R.C.P.L., Sydney, N.S.W.
Cave, Frank Evans, L.R.C.P.L., Lee.
Close, John Borrill, L.S.A., Hull.
Cottam, Francis Henry, Crumpsall, near Manchester.
Coombe, Russell, West Kensington.
Cranstoun, Charles Bruce, M.B. Durh., Ludlow, Salop.
Drew, Henry William, Blackman-street.
Gledden, Alfred Maitland, Hornsey-lane.
Goullet, Charles Arthur, L.R.C.P.L., St. John's Wood.
Howse, Neville Reginald, Barking-road.
Nott, Arthur Holbrook, Devizes.
Rickards, Henry William, Russell-square.
Rivers, William Halse Rivers, Offham, Kent.
Robinson, Bernard, L.R.C.P.L., West Kensington.
Smith, Henry Archibold, Leeds.
Thompson, James Edwin, Northwich.

Admitted on the 26th inst.:—

Branson, Herbert William, L.R.C.P.L., Westbourne-park.
Brock, Ernest Henry, South Norwood.
Castle, Charles Wigram Marshall, L.S.A., Blackheath.
Comber, Charles Thomas Thornton, L.R.C.P.L., Kew.
Fisher, Theodore, Greenwich.
Goodale, Henry, Argyll-road.
Hawkins, Francis Stanhope, Trinity-square.
Hamer, William Heaton, Highgate.
Holder, Sydney Ernest, Adelaide, South Australia.
Kelsall, Henry Truman, Westward Ho!
Nihill, John Edward, Melbourne.
Potts, Frank Reginald Henry, Amersham.
Seville, Charles Frederick, L.S.A., Manchester.
Smith, Henry Sandford, Surbiton.
Waite, Davis Allan, Hampstead.
Wilbe, Richard Haydock Wiffin, Finchley-road.

Admitted on the 27th inst.:—

Booth, Oscar Milner, Thorner, near Leeds.
Castle, Bernard, Guildford-place.
Clarke, William Frederick, Lincoln.
Farrow, Frederick, Ardwick, Manchester.
Fisher, William Teston, L.R.C.P.L., Bembridge, Isle of Wight.
Harrop, George Burton, Stalybridge.
Hounsell, Frederick Claude, Bessboro'-gardens.
Hinde, Alfred Buckley, L.R.C.P.L., Guernsey.
Owen, John Vaughan, Machynlleth.
Routh, William, Wandsworth.
Sandol, John Warden, Bodmin.
Sinder, Charles Edward, Regent's-park.
Tomkins, Alfred John, Clifton, Bristol.
Volland, John Horatio, L.S.A., Birkenhead.

ROYAL COLLEGE OF PHYSICIANS IN IRELAND.—At the July examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Julia Maria Brinck, John Evans, John Edward Foster, P. T. Bolger, Frederick William Burnett, Charles James Counihan, Robert Hankam Cox, John Thomas Crincon, James Edward Joseph Duffy, Victor Edward Fenton, Michael Joseph Geary, Godfrey Goodman, Sinclair A. Long, J. Best McBride, Philip M. McDermott, Francis Joseph McGuire, William Kirkpatrick Macilobert, Cornelius Riordan Moloney, Patrick Thomas Morrosey, Jeremiah Edward Nally, William Porritt, Everard Marcus Power, Herbert Newman Pullan, John Rafter, Charles Augustus Ridal, Alfred John Septimus Roe, William Livingstone Ross, Charles Scatchard, John C. Sellars, Edward Ernest Smith, James Henry Stewart, William Francis Stritch, Charles Philip Tennant, Percival John Ternall, Frederick Whitfield Thornton, Thomas Fowler Wade, Thomas Williams, Robert James Wood, David Thomas Wylie, E. Yeates, John Thomas Yoakley.

MIDWIFERY.—Harvey Moore Brabazon, Robert H. Cox, James E. Duffy, Michael J. Geary, Godfrey Goodman, John Best McBride, C. R. Moloney, Wm. Norman Murphy, Jeremiah Edward Nally, William Porritt, Charles Augustus Ridal, Wm. Livingstone Ross, John C. Sellars, Edward Ernest Smith, William F. Stritch, Thomas Williams, Robert J. Wood, David T. Wylie, Edward Yeates.

The under-mentioned have been admitted Members:—

Otho Galgey; William John Read Rainsford.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following, having recently passed their final examination for the Letters Testimonial, have been admitted Licentiates of the College:—

Ormsby Burkitt, Charles J. Counihan, James D. O'Dowd Egan, Francis E. Gahagan, Timothy H. Hannigan, Gerald Lake, David M. Lindsay, John J. Myres, John J. O'Connell, Edward B. Pooley, Walter Swan, George Woods.

Thirty-two candidates entered for examination; two withdrew, two were absent, and sixteen were rejected.

At a Supplemental Examination, held on the 19th inst., the undernamed were admitted Licentiates of the College:—

James E. Duffey, William S. D. Exeter Jordan, and F. W. Mousell.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 22nd inst.:—

Armitage, Joseph Hartman, Montreal, Canada.
Close, John Borrill, Florence-avenue, Hull.
Hawkins, Frank Sidney, M.R.C.S., Berkeley-square, Bristol.
Williams, James Francis, Montreal, Canada.

THE death is announced of Dr. Cajetan Anton Kranz, chief vaccination physician in Bavaria.

THE sanitary staff of Clerkenwell have seized 12,000 bad eggs; and as the Sanitary Act provides for the prosecution of vendors of "fish, flesh, or fowl unfit for human consumption," counsel's opinion is being taken as to which of these heads the eggs can be placed under.

SMALL-POX has appeared at Kirkby Stephen, Westmoreland, causing some alarm in the district. The sufferers have been removed to the fever hospital in connexion with the workhouse. The desirability of building a hospital for patients suffering from infectious diseases is to be discussed by the local authorities.

WORCESTER INFIRMARY.—This institution has been very fortunate lately in the receipt of large donations and bequests of money, and a new wing is about to be added to the building. One anonymous doner has given £5000 on condition that his name shall not be divulged during his lifetime.

CATERHAM IMBECILE ASYLUM.—On the 24th inst., the members of the Metropolitan Asylums Board paid their annual visit to this asylum, and thus concluded the circle of summer inspections of the institutions under its charge. The asylum, which is built upon the block system, contains accommodation for 2050 patients, and during the sixteen years it has been built nearly 4000 lunatics have been received. The result of the inspection is reported to be satisfactory.

UNIVERSITY COLLEGE, LONDON.—Mr. J. M. Horsburgh has been appointed secretary, to enter upon his duties on October 1st.

AT an inquest held at Liverpool on the 27th inst., on the body of a man who had died in the Southern Hospital, the jury returned a verdict of death by misadventure in the administering of chloroform.

ACCIDENT AT THE NEW MEDICAL EXAMINATION HALL. On Thursday a part of the material, consisting of several large blocks of stone, ready to be placed in the new building, fell from the top of the western side of the structure on to the scaffolding, which was so damaged as to become dangerous to passers-by. Fortunately, no one was injured, as the scaffolding at the time was unoccupied.

NEW LUNATIC ASYLUM.—At a meeting of Middlesex magistrates on the 22nd inst. it was resolved, on the motion of Mr. A. W. Gadesden, that the agreement entered into by a special committee appointed to provide an additional asylum for pauper lunatics for the purchase of a part of the Claybury Hall Estate, Woodford, Essex, consisting of 250 acres, for £36,000, be approved and confirmed.

VOLUNTEER MEDICAL STAFF CORPS.—The first annual competition for the subscription challenge shield took place on the 24th inst. at Wellington Barracks, and resulted in a victory for the No. 4 (lay) company, Surgeon-Major J. Hornsey Casson commanding. This competition is the outcome of the exertions of the adjutant of the corps, Surgeon Lees Hall, who has done much to promote the welfare of the corps. Surgeon-Major T. Faris, of the Victoria Hospital, Netley, acted as judging officer.

HOSPITAL SATURDAY FUND.—The amounts which have up to the present time reached the central office on behalf of this fund show a considerable falling off as compared with last year's street collection—a condition of affairs attributable, without doubt, to the extremely unfavourable weather which prevailed at the time of the appeal. The deficiency amounts to some £500 or £600. A larger number of institutions have, we learn, applied to participate in the fund than heretofore.

ESSEX AND HERTS BENEVOLENT MEDICAL SOCIETY.—The 100th anniversary court of audit of this Society was held on the 20th inst., when grants amounting to £330 were made. According to the rules, medical men desirous of becoming members must do so within three years after their settling in the counties of Essex and Hertford, but at this meeting it was resolved that the year 1887 be considered as a year of grace, in which medical men having resided in these counties for periods exceeding three years may be admitted as members of the Society upon payment of an entrance fee of one guinea for every year of residence exceeding three. This resolution will, it is hoped, have the effect of largely increasing the Society.

OPPOSITION TO PASTEUR.—On the 25th inst., at a meeting held at Paris and presided over by Dr. Chassaing, a municipal councillor, the methods of M. Pasteur were attacked by several medical men and veterinary surgeons. One speaker, M. Paul Bouiller, contended that microbes were not the agents but simply the products of decomposition. The very same microbes found by the Professor in mad dogs could be equally obtained from the bodies of persons who had died of consumption. Dr. Bouiller concluded by challenging Professor Pasteur to be bitten by a really mad dog. He (Dr. Bouiller) would submit to be bitten by the same animal. It would then be seen that the Professor would go mad, and that he (Dr. Bouiller) would have cured himself by simple cauterisation.

WATER SOFTENING.—On the 24th inst. a visit by the mayors and members of several corporations and a number of borough and other engineers and gentlemen interested in water-supply and sanitary matters was made to the waterworks at Henley-on-Thames to inspect the water softening and purifying apparatus erected there in 1882 by the Atkins Filter and Engineering Company. The whole of the town water-supply is treated by the process, which consists in softening the water by means of lime, and filtering it within the compass of a machine house. The system, which has worked satisfactorily, has recently been carried out for treating the water-supply at Wellingborough, and has also been adopted by the corporation of Southampton for softening and filtering the whole town supply of between two and three million gallons per diem.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BATTEY, H. A. W., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the First District of the Petersfield Union.

BUSH, F. A. A., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Bishopstone District of the Wilton Union.

CRUBB, WILLIAM L., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Sandgate District of the Elham Union.

CLARKE, ARTHUR C., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Middleton Cheney District of the Banbury Union.

DALY, ED. O., M.A., M.D.Oxon, M.R.C.P.Lond., has been appointed Honorary Physician to the Hull Royal Infirmary, vice Owen Daly, resigned.

DALY, OWEN, B.A., M.D., F.R.C.P.Lond., has been appointed Honorary Consulting-Physician to the Hull Royal Infirmary.

DAVIDSON, P., M.A., M.B., has been appointed Honorary Physician to the Liverpool Infirmary for Children, vice E. H. Greves, resigned.

FLETCHER, FREDERICK A. C., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Kildwick District of the Skipton Union.

JOVELL, T. MARK, F.R.C.S.Ed., has been appointed Lecturer on Diseases of the Throat at the London Hospital Medical College.

KNN, W. JOSEPH, M.D., F.R.C.S.E., has been appointed Honorary Consulting-Surgeon to the Hull Royal Infirmary.

NON, ADAM C., M.D., C.M.Aber., has been appointed Medical Officer for the Scrooby District of the East Retford Union.

PETTERSEN, JOHN, M.D. St. And., M.R.C.S., has been appointed a Public Vaccinator for the Parish of Liverpool, vice Speer, deceased.

STEEVES, G. WALTER, B.A., M.D., M.R.C.S., has been appointed U.S. Sanitary Inspector at the Port of Liverpool.

Births, Marriages, and Deaths.

BIRTHS.

BARTON.—On the 15th inst., at Brookwood, Surrey, the wife of Jas. E. Barton, M.R.C.S., of a daughter.

JAKINS.—On the 22nd inst., at 9, Osnaburgh-street, Regent's-park, the wife of Percy S. Jakins, M.R.C.S., of a son.

MOULLIN.—On the 27th inst., at Highgate, the wife of C. W. Mansell Moullin, F.R.C.S., of Wimpole-street, W., of a son.

SIMPSON.—On the 25th inst., at Midlothian, the wife of Prof. Simpson, of Edinburgh, of a son.

TIPPETTS.—On the 11th inst., at Abingdon, Barbadoes, the wife of Deputy Surgeon-General A. M. Tippetts, Medical Staff, of a daughter.

MARRIAGES.

DALTON—HODGES.—On the 21st inst., at St. Andrew's, Derby, Charles Bernard Dalton, M.R.C.S., of Derby, to Kate, eldest daughter of William Henry Hodges, of Ash Tree House, Derby.

MORLEY—SAVAGE.—On the 21st inst., at Woodford, Richard Basil Morley, M.R.C.S., L.R.C.P., to Elizabeth, daughter of William Savage, Esq., J.P., of Port Elizabeth, South Africa, and of Woodford, Essex.

WILLETT—GREGSON.—On the 24th inst., at St. Saviour's Church, Eastbourne, Edmund Willett, M.D., to Harriette, widow of Alfred Knight Gregson, of Lowlynn, Northumberland.

WILLIAMS—NICHOLS.—At St. Pancras Church, Montagu Wm. Williams, M.R.C.S., L.R.C.P., &c., of High-cross-street, Leicester, to Ida Maria, eldest daughter of D. Cubitt Nichols, of 31, Brunswick-square, W.C.

WILLIAMSON—MILLER.—On the 22nd inst., at the Cathedral, Newcastle-on-Tyne, George Edward Williamson, F.R.C.S., to Minnie, only daughter of Thos. R. Miller.

DEATHS.

JESTON.—On the 18th inst., at his residence, Henley-on-Thames, Thos. Ward Jeston, late Surgeon of the 38th Regiment in the Peninsular War, in his 97th year.

KIERNANDER.—On April 1st, at Gloucester-road, Kew, Sydney Herbert Campbell Kiernander, late Surgeon, P. and O. Company.

MOXON.—On the 21st inst., at Finsbury-circus, Walter Moxon, M.D., Physician to Guy's Hospital, aged 50.

TROWSDELL.—On the 23rd inst., at Waterloo-road, Dublin (suddenly), William G. Trowsdell, M.D., Surgeon-General, in his 71st year.

TUDOR.—On the 26th inst., at his residence, Church-view, Bootle, near Liverpool, Richard Archur Tudor, F.R.C.S., aged 88.

WARWICK.—On the 23rd inst., at Cambrian-villas, Queen's-road, Richmond, Richard Warwick, F.R.C.S.E., in his 81st year.

WILSON.—On the 19th inst., at 52, Rodney-street, Liverpool, Mary Morgan, wife of James Wilson, M.D., aged 32.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

DON QUIXOTE FROM A MEDICAL POINT OF VIEW.

DR. DON EMILIO PI Y MOLIST, who is described as the "doyen" of Spanish alienists, has recently published a work, entitled "The Beauties of Don Quixote from a Medico-psychological Point of View, with General Remarks on Madness and a New Commentary on the Immortal Novel," with which the profession in Spain are greatly delighted, and a grand banquet has just been given to Dr. Pi in Barcelona, as a mark of the appreciation of his professional brethren of the work referred to. As "the immortal novel" is read by thousands of foreigners, it is to be hoped that someone will have the goodness to translate Dr. Pi's new work into some language more universally read than Spanish.

"THE INSUFFLATION OF IODOFORM INTO THE TRACHEA AFTER TRACHEOTOMY FOR DIPHTHERIA."

To the Editor of THE LANCET.

SIR,—In your issue of July 24th appears a paper by Mr. George Shirres, M.B., headed as above. No mention is made in the notes of the two cases as to the state of the urine, or whether any paralytic phenomena supervened. Nor is it shown whether other cases occurred in connexion with either of those recorded. The grounds therefore for the diagnosis appear to me to be insufficient, and in the absence of these data the value of the method recommended must still remain doubtful. I hope Mr. Shirres will favour us with some statement in reference to the questions raised by me.

I am, Sir, your obedient servant,

LEWIS W. MARSHALL, M.D.,
Nottingham, July 26th, 1886. Hon. Surgeon, Children's Hospital.

N.B.—The whole period of convalescence seems to be exceptionally short, and the time during which a tube was required is very much so in my experience.

LUNATIC ASYLUMS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—I am anxious for information about lunatic asylums in Switzerland, and do not know how to obtain it. Perhaps some reader of THE LANCET could tell me at what places in Switzerland such asylums are to be found. This would greatly oblige me.

Believe me, Sir, faithfully yours,

July 24th, 1886. F. F. G.

FLIES AS SANITARY INSPECTORS.

THE *Sanitarian* records an instance of flies acting as sanitary inspectors. In one of the rooms of a residence in an American city offensive odours were detected, but their exact source could not be located. The carpets were raised, and a carpenter was engaged to take up the entire floor. At this moment a visitor suggested that an appeal be made to the instinct of the fly. Two "blue-bottles" were accordingly brought from a neighbouring stable, and the doors and windows of the room closed. The flies soon settled upon one of the cracks in the floor, and when the boards were raised at this point a decomposed rat was found.

Mr. C. R. Davidson.—1. We do not know.—2. Dr. D. Powell's work (Lewis, *16s.*).

Mr. T. Forster's paper is marked for early insertion.

"NEURORHEUMA."

To the Editor of THE LANCET.

SIR,—I think it was in THE LANCET that I read, a few years ago, an article in which the increasing manufacture of new-fangled names, barbarously fashioned from the Greek and Latin, was strongly deprecated; and aspiring youths, such as juvenile physicians and physiologists, had administered to them some sound advice about giving more attention to the understanding and use of old English. Now, when we are threatened with so terrible a jaw-breaker as "neurorheuma"—which reminds one of our old friend, "truly rural," the famous speech-test for drunkenness—as a substitute for the well-understood "nervous energy," it is time to enter a protest against innovations which are as absurd as they are useless. Dr. White desires to help the learner; but I think he is putting a hindrance in the learner's way. To students "neurorheuma" will have as little meaning as the chorus "tooral-looral," and not half the fun. I have often been pained to see the student get more and more confused and addle-brained while trying to translate into English some of our more recent class-books, especially those treating of physiology and eye diseases. In class-books on other subjects of study authors, for the most part, endeavour to make matters simple and easy for the learner; but in the study of medicine the unfortunate student is becoming with every advancing year more hampered by the encumbered style of authors, or rather, compilers, whose sentences are often a mere jargon of words derived from Latin or Greek. And yet that science can be dealt with by the use of simple language may be seen in such works as Faraday's Researches, Herschel's Astronomy, Arnot's Physics, Draper's Physiology, and Watson's Practice of Medicine. In some of the earlier numbers of *Good Words* there are articles by Sir J. Herschel on abstruse subjects in astronomy; and if those articles had not been written in plain and popular language they would not have been admitted into a popular journal.

But Dr. White's "neurorheuma" is not scientifically exact. He gives neurorheuma as meaning "that which flows along a nerve." But nervous energy, *alias* neurorheuma, is not alone in flowing along a nerve; there are molecular changes, physical, chemical, and vital, quite distinct from nervous energy, which continually go on throughout the whole nerve tissue. "That which flows along a nerve" is therefore too vague a phrase to define the nature of nervous energy. Dr. White's remarks about the absurdity of calling electricity the "wiry flow," the "wiry current," &c., are right enough. But the same remarks do not hold good when applied to nervous energy; for electricity can be transmitted through various kinds of matter besides metallic wire, whereas nervous energy is that peculiar form of energy which the nerves alone convey; and therefore the term "nervous energy" is a most appropriate one to employ until we shall have learned something more about the nature of the various forms of energy (heat, light, electricity, &c.) and their relation one to another. Within the last few years many additions have been made to our knowledge on this subject; and it is well to wait for further knowledge before committing ourselves to the use of so vague a term as "neurorheuma."

Many deep thinkers have tried to answer the question, What is life?—with as much result as Pilate had from his query about truth. Dr. White, however, has found, at least to his own satisfaction, the solution of the question, and the best possible definition of life. According to him, it is the capability of the cardiac and respiratory systems to transmit "neurorheuma." It is to be hoped that his readers will see through this definition without their "mind's eye" becoming troubled with *rheuma*, and that the science of biology will be greatly advanced thereby.

I am, Sir, your obedient servant,

July 26th, 1886. THORBURN PATERSON.

"PERIODICAL BILIOUS ATTACKS."

To the Editor of THE LANCET.

SIR,—In response to the appeal of your correspondent, "L.R.C.P." (July 24th), regarding a case of periodical bilious attacks, I would suggest two "working hypotheses." The first is based upon the length of interval between the attacks, and suspects the menstrual sinus, with disorder of some of the pelvic viscera and attendant reflex disturbance of the ganglionic system. The second refers to a possible malarial origin, so long an interval, with regularity of attack, being matters of not infrequent occurrence where such agencies are rife. Here, too, the influence of heredity may be an interesting factor as regards etiology and prognosis. I am, Sir, very respectfully yours,

Ilford, Essex, July 26th, 1886. H. JONES, M.D. (U.S.A.)

THE BLACKBURN AND EAST LANCASHIRE INFIRMARY.

OUR attention has been directed to a controversy which has arisen between the Board of Management and the medical staff of the above institution, and which has been set forth by letters that have appeared in the *Blackburn Times* from the board on the one hand and the medical officers on the other. The main point in dispute appears to be whether it is necessary or desirable that the dispenser to the infirmary should possess a legal medical qualification. The view taken by the medical staff on this question is an affirmative one, whilst the board express an opposite opinion, and, in a kind of manifesto, resent the interference of the staff in the general management of the charity. A good deal of feeling seems to have been imported into the controversy, arising, we apprehend, from some peculiarity in the mode of working of the internal affairs of the infirmary. Speaking generally, however, we may say that, though, as a rule, it is not regarded as essential that a dispenser should be a registered practitioner, yet it must be conceded that the medical staff of a hospital are the best judges of what may be required to render thoroughly efficient the medical and surgical treatment of the patients who enter its walls, and that they are justified in seeking to express their views on the matter in any legitimate way.

R. H.—Yes. In cases where the rupture can be easily kept under control by a truss, the best kind to wear is one having a pad composed of ivory, celluloid, or vulcanite. The spring of the truss should be covered with celluloid or vulcanite, or nickel-plated and then covered, the cover being easily changed. As a rule, those pads which are composed of indiarubber soon wear out. Any instrument-maker will supply the truss.

THE USE OF COCAINE IN CIRCUMCISION.

To the Editor of THE LANCET.

SIR,—I send you short notes of a case in which cocaine proved a complete success. The operation being a common one, and very painful, is now rendered painless by the harmless procedure of subcutaneously injecting a solution of the muriate of cocaine.

Two days ago, on shore at Halifax, I performed the minor operation of circumcision on an adult aged twenty-four, using cocaine as a local anæsthetic. Two grains dissolved in ten minims of water were injected into the prepuce, one grain (five minims) on either side, and in a few minutes the operation was completed. The patient sat up and watched the proceedings with interest. The effect of the drug was most satisfactory, the operation being painless.

I am, Sir, yours obediently,

A. G. P. GIPPS, L.R.C.P., &c.

H.M.S. *Heliorophon*, at Halifax, July 12th, 1886.

To the Editor of THE LANCET.

SIR,—In your issue of July 17th is a letter from Mr. Atkinson of Kensington, describing a case of circumcision under the influence of cocaine, and I notice another in your issue of the 24th from Mr. Jackman of Coggeshall. The following brief notes bear out their experience.

A short time ago I determined to circumcise myself, and commenced to incise the prepuce; but this I found extremely painful. I then well painted the prepuce, both inside and out, with a 4 per cent. solution of hydrochlorate of cocaine, and injected into the prepuce in front a few drops of it; but I found that the insertion of the needle and subsequent injection caused me a good deal of pain, and I did not repeat it. After waiting a few minutes I proceeded to cut again, and found that the anterior part of the prepuce was quite anæsthetised, though cutting through the posterior part was very painful work. I then inserted six catgut sutures, and, with the exception of some venous hæmorrhage thirty-six hours after, and which was easily stopped, the result has been satisfactory. Nevertheless, if I possessed a second prepuce requiring removal, I think I should obtain the aid of a professional brother, and not repeat the experience of being both operator and patient at the same time. I am, Sir, yours obediently,

July 26th, 1886. L.R.C.P. Lond.

SAD FATE OF A GERMAN PRACTITIONER IN SOUTH AMERICA.

THE German residents in Bolivia, wishing to obtain the services of a resident practitioner of their own nationality, recently agreed to guarantee some £600 a year towards his support, and to allow him, besides attending the subscribers, to practise privately. A suitable gentleman was obtained, but unfortunately he shortly afterwards became insane. No satisfactory asylum being available in Bolivia, the German colonists tried to send him to Europe for treatment; but, though they offered a free return passage and a liberal recompense, they were unable to find anyone who would take charge of the unfortunate doctor. However, from want of sufficient attendance, he managed to escape, and nothing was heard of him till, three days later, a party of Indians brought him back with both his legs crushed. He was still alive, but was evidently fatally injured.

Dr. W. Thorburn (Rusholme).—The charts are printed and published by H. Silverlock, London.

CULTURE OF VACCINE IN MUSHROOM JELLY.

EXPERIMENTS have recently been made by the Finnish Medical Society in the cultivation of artificial lymph in sterilised mushroom jelly. The artificial lymph has also been dried and used for vaccination. A child was exhibited at one of the meetings who had been vaccinated by the artificial lymph in the arm. There were nine vesicles in three rows. They were all well developed, and did not present any dissimilarity, although two rows had been produced with lymph taken from different parts of the culture glass, and the third row with dried lymph from the same glass. Former experiments had not been so successful, owing to the resistance of the lymph to the effects of drying. The cultivation of the lymph has now been brought to a more satisfactory point.

Inquirer.—In the absence of an agreement, we think three months notice should be given.

THE ARMY MEDICAL STAFF.

To the Editor of THE LANCET.

SIR,—I am glad to see that in some recent issues of the medical papers attention has been called to the pay of the junior army surgeons in India. The young surgeon is induced to enter the service under the mistaken delusion that he is to receive pay at the rate of £300 per annum, with the allowances of a staff captain, which altogether amounts to nearly £300 per annum. This he undoubtedly receives during the few months he is allowed to remain at home; but on arriving in India (usually within his first year of service) he finds that though he continues to wear the badges of rank of a captain, according to the Indian Army Regulations he ranks with a lieutenant for the first six years of his service, and draws the allowances of that rank only, which, together with his pay, amount to 317½ rupees per month (value of exchange being 1s. 5½d. the rupee); this is 132½ rupees less than the pay of a regimental captain, 82½ rupees less than that of a junior veterinary surgeon, and actually 7½ rupees less than the pay of a young subaltern on becoming probationer for the Indian Staff Corps. But this injustice fades into insignificance when compared with what follows after the surgeon attains five years' service. At home after this period of service his pay is augmented by £50 per annum (equivalent to 58 rupees 5 annas per month), while in India he gets the overwhelming addition of 18 rupees 12 annas per month, being at a loss of 40 rupees 1 anna for the privilege of serving in that unhealthy climate. Nor is this all. At home, when travelling on duty, the surgeon receives an allowance of 10s. per day, while in India not only does he receive no such allowance, but has to provide himself with tents and transport for his baggage. Again, though the nature of his duties always necessitates his being mounted, he is not allowed horse allowance, except when actually marching with troops, though (I suppose as a sort of grim joke) the dress regulations authorise him to wear spurs.

I hope you will find space to publish these few facts, if only in justice to intending candidates, who, I am sure, are about to enter the service, as many have done, under false impressions.

I am, Sir, yours faithfully,

July, 1886. ONE WHO SPEAKS FROM BITTER EXPERIENCE.

"AN APPEAL."

To the Editor of THE LANCET.

SIR,—Referring to my appeal in THE LANCET of June 26th and the list of subscriptions you kindly inserted on July 10th, I have since received the following sums, and trust that those of your readers who have not yet contributed will not overlook this very deserving case.

I am, Sir, yours faithfully,

R. FITZROY BENHAM.

Abercorn House, Baron's Court, London, S.W., July 27th, 1886.

TOUTING PRACTICE IN LEICESTER.

CARD sent us from Leicester is very unprofessional. It appears to be indiscriminately circulated, and offers attendance in general cases, with "special departments in throat cases and in diseases of women," on low terms. The names appended to the card are "Dr. Dickson, Physician and Surgeon. Assistant, Mr. Anderson." It is dated from 2, Foundry-square, Belgrave Gate, Leicester. It is to be regretted that Mr. Dickson did not consult the Colleges from which he obtained his diploma before resorting to such advertising methods.

Inquirens.—Until the College alters its Bye-laws the title of "Dr." cannot be used on the ground of the qualification mentioned. "Physician and Surgeon" are the proper titles to indicate the qualifications.

BLACKBERRIES.

A CORRESPONDENT writes:—"Perhaps one of the most interesting problems is the inquiry into the reasons why certain plants and animals have been chosen for cultivation by man, and others, apparently quite as suitable, rejected. The blackberry has not found favour. Attempts are at present being made to introduce varieties of this fruit, which, both by appearance and flavour, seems suitable for cultivation. Unfortunately, the blackberry, though dear as a remembrance of our youth, when all things were more or less digestible, does not commend itself to our riper years, from its tendency, either raw or cooked, to produce intestinal irritation. An examination of the numerous seeds in a ripe blackberry shows them to be, not as in currants, gooseberries, &c., smooth and polished, but covered all over with curved Arabesque patterns with sharp edges, forming a very pretty "common object for the microscope" with a low power, but in masses in the intestines undoubtedly out of place. Until, therefore, our gardeners can give us a smooth-seeded blackberry, it is wise to use the blackberry only for the preparation of jelly, after the manner of red currant jelly, or as blackberry vinegar. In these, the seeds being rejected, the delicious flavour of the fruit can be enjoyed without fear of colic or dysentery."

M.D.—We regret we cannot assist our correspondent in the way he desires.

Student should apply to the Secretary of the College.

COCAINE IN AMPUTATION OF FINGERS.

To the Editor of THE LANCET.

SIR,—Seeing in last week's issue of THE LANCET reports of some cases of circumcision under the influence of cocaine, I thought it might be interesting to relate an instance which recently came under my observation, in evidence of the utility of this anæsthetic agent in amputation of the fingers.

The patient was a woman aged about thirty-five. After the injection of five minims of a 4 per cent. solution in three places (fifteen minims in all) around the site of amputation, the operation was performed without the slightest discomfort to the patient, she being engaged in conversation meanwhile with a friend. It was found necessary to remove a portion of the second phalanx with the bone forceps, and even this evoked no sign of pain, the patient stating that she heard the bone go, but felt nothing. The operation throughout, including the application of torsion to a small artery, of two wire sutures and dressing complete, was performed quite painlessly and without any reapplication of the cocaine.

I am, Sir, yours obediently,

E. ATHERDEN THOMPSON.

Westminster Hospital, S.W., July 24th, 1886.

TWINS.

To the Editor of THE LANCET.

SIR,—Perhaps some of your readers may be interested to read the following notes of an, at least to me, unusual case.

A. T—— sent for me to attend her in her second confinement on Saturday last, at 7 P.M. After a very powerless labour, the first of twins was born at 11.20. I could just feel the membranes with vertex of the second child, but could not reach well enough to rupture them had I desired. After putting on a binder and waiting an hour or so without any evidence of uterine action, I gave several successive doses of ergot, but without any result. I waited till 4 A.M. on Sunday, and then left, as there was absolutely no pain, and no hæmorrhage or any other indication for immediate interference. I was glad also to have the opportunity of looking in the books to see what was the correct thing to do in such cases. I could not get any definite opinion as to the necessity of waiting or not, so I left matters as they were, and continued to be until Monday at 8 P.M. The patient had slept well and eaten well, and I could hear the fœtal heart. The only indication for delivering seemed to be the state of the funis of the first child, which was changing colour, and I thought, considering the sultry weather, it was unadvisable to wait any longer. Having given a few more doses of ergot, I was able to rupture the membranes, and at 12.15 A.M. on Tuesday I delivered the second child with forceps put on at the brim. There seemed to be no reason for the lingering course of the second birth beyond the powerless pains. Twelve hours after all was well with mother and children, either of which latter would have been a respectable single birth.—I am, Sir, yours truly,

July 27th, 1886. M.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Lectures
ON
DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

BY HENRY POWER, F.R.C.S.

LECTURE I.—PART II.

DISEASES OF THE LACRYMAL GLAND.

Fistulæ.—Fistulæ of the ducts of the lacrymal gland are occasionally congenitally present. A typical case is recorded by Steinheim,[1] who observed it in a girl fourteen years of age, and gives the following description of it. On the outer third of the right upper lid, four or five lines from the edge, a little funnel-shaped opening lined with hairs resembling those of the eyelashes ran upwards under the skin. From this opening tears continually trickled and fell in large drops over the cheek. The little opening was so concealed that even after removal of the hairs it could not be seen, but a fine sound could be passed in two or three lines. Compression of the opening by forceps, one limb of which was passed under the lid, showed that the duct ran upwards and outwards. This condition had existed from birth. Such fistulæ almost invariably open by the skin, but Jarjavay[2] has reported one case that fell under his observation in which the passage opened by the conjunctiva. As a rule, fistulæ of the ducts of the gland proceed from injuries in which cicatrisation has been imperfectly accomplished, or from the extension of disease from adjoining parts. Thus Jarjavay[3] records a case where after the cicatrisation of a wound of the right side with a dagger a small opening was left, which communicated with a sac the size of a small almond. When tears were excited to flow the tumour enlarged, and by pressure and manipulation a stream of clear fluid could be made to exude. Arlt[4] has noticed a case where one of the ducts appears to have been opened by the advance of a rodent ulcer. Such fistulæ are very difficult to heal, and many methods have been tried to effect their obliteration. Beer[5] gives one case in which he effected a cure by a means that for some reason, though successful here, he does not recommend to be repeated in other cases of a similar nature. The fistula was five millimetres long, and the patient was a healthy young peasant. Beer heated a knitting-needle red hot, and buried it quickly in the passage, rotating it two or three times: complete recovery took place. By others the galvano-cautery and various caustics have been tried. Sir W. Bowman's case, reported in the first volume of the Ophthalmic Reports, has become classical, and several have been cured by the same proceeding. It essentially consisted in converting a fistula opening cutaneously into one opening by the conjunctiva. A threaded needle was passed through the external opening and a little way up the passage, and was then made to perforate the conjunctiva; a second needle on the same thread was passed straight through the lid at the external orifice, and the two ends were tied so that they included a portion of the conjunctiva. The edges of the external orifice were refreshed and a cure resulted.

Cysts.—Cysts of the lacrymal gland seem to be divisible into two classes—viz., retention cysts and hydatid cysts. Retention cysts result from the closure of the external orifice of one of the excretory ducts, and this may occur from injury or from some inflammatory affection of the conjunctiva. The tumour is usually of small size, but interferes with the movements of the globe, and the patient applies for relief. On raising or everting the upper lid and directing the patient to look downwards and inwards, a semi-transparent bluish swelling appears. On pressure it is found to be elastic, and the conjunctiva glides over it. Occasionally it may be made to discharge its contents, which are watery, and contain a small proportion of albumen. Such a tumour is named a "dacryops." There is usually very little pain or inflammatory trouble. In von Graefe's case there was a slight access of inflammation about once a fortnight, when the tension of the retained fluid seemed to burst through some obstruction and relief was obtained. The disease is chronic.

Dubreuil[6] has reported a typical case of cyst of one of the excretory ducts of the lacrymal gland. The patient, a woman aged thirty-five, presented a tumour between the eye and the eyelid of the size of a nut. It was covered with the conjunctiva, and was a little redder at its lower part than above. On raising the lid it projected strongly; on closing the lid it retreated. It had existed for a year, arose without apparent cause, and was fluctuating, translucent, and indolent. It augmented in size when she wept, but there was no diminution in the visible quantity of tears. Vision was good, and the movements of the globe were only slightly impeded. Dubreuil everted the lid, made an incision parallel to the border, and reflected the thin conjunctiva. The cyst was then opened, giving exit to a spoonful of serous fluid. The anterior wall of the tumour was cut away with curved scissors; slight swelling followed, and complete recovery ensued. The epithelium was columnar, showing it to be part of the duct.

Injection of the sac with diluted tincture of iodine has been tried, but there is considerable risk of acute inflammation of the surrounding tissue—an inflammation that may seriously interfere with the movements of the globe and with vision, and is not, therefore, to be recommended.

Of *hydatids* of the lacrymal gland no one has treated better than Chelius,[7] who remarks that these cause by their pressure on the eye the same troubles that result from other tumours, although from their usually rapid development the troubles become more marked, and vary in accordance with the presence or not of inflammation. If the globe be inflamed, the patient experiences at first a feeling of weight and tension at the back of the eye, which becomes very troublesome in the course of from eight to fourteen days, especially when the eye is moved. The patient feels as if the eye were being constantly pressed forward, but Chelius is particular to remark that neither the form of the globe nor of the eyelids is affected, nor are the functions of the eye impaired. The sense of pressure increases to pain extending over half the head. The globe begins to be really protruded and the surface becomes dry. Retinal troubles are felt, fiery sparks and colours, temporary loss of vision, and diplopia. In the fourth week the pain is unbearable, and constitutional disturbance results from the attendant loss of appetite and sleep. The globe protrudes so that the lids cannot be closed. If the finger is pressed between the margin of the orbit and the globe, no distinct tumour but a general sense of hardness is felt. Vision fails, the eye becomes hazy and flaccid like that of a dead man, and indeed death itself is not far off, supervening with the symptoms of apoplexy, and the patient dying with coma. If exophthalmos occur early, the general symptoms and pain are less severe, but the eye is lost early with hypopyon. In regard to treatment, early evacuation and removal are to be adopted, and the cavity should be stuffed with charpie. The cyst presents at the mouth of the wound and can be extracted, and the wound then heals. Wharton Jones[8] has recorded one case of this disease, Fehre a second, and, according to Abadie, Benedict a third. I cannot say I have seen any case in which the presence of a hydatid cyst has been demonstrated, and it is a rarely mentioned disease in recent journals. One case is given in M. Galezowski's *Recueil d'Opthalmologie* for 1885, ser. iii., an. vii.; but the reference in the index is incorrect, and I have not been able to find it in the body of the volume. It is headed "Hydatique (Kyste) substitué à la Glande Lacrymale." But the symptoms given by Chelius and others are fully supported by the record of numerous cases of hydatid cysts of the orbit given by Dieu,[9] who practised in Algeria, where hydatid cysts appear to be of common occurrence. The disease is not mentioned by Stellwag, von Carlon, Deval, nor by many other writers.

Arlt[10] states that he has met with one case of atrophy of the gland in the dead body, and in this it appeared to result from obliteration of the ducts consequent upon trachoma. I have not been able to find any other instance of this affection.

Syphilitic inflammation of the lacrymal gland has been occasionally noticed. Thus Dr. Bull[11] reports a case of this lesion which occurred in a patient who was deeply syphilised, and ultimately died from meningitis and syphilitic tumours of the dura mater. On examination, the lacrymal gland was found to be hypertrophied and inflamed, in consequence of inflammation and general infiltration of the tissues of the orbit, which, again, was dependent on diffuse orbital periostitis. There was a high degree of exophthalmos, and enucleation of the eye and the evisceration of the orbit were required to calm the excessive pain. The lacrymal gland was hypertrophied; but this hypertrophy was only due to a hyperplasia of the elements of the areolar tissue, and not of the glandular tissue.

An analogous case has been given by Mr. Streatfeild,[12] whose early death we have so recently had to deplore. In this case the inflammation seems to have originated in the gland itself. A nodulated swelling occupied the position of the gland, which was well defined in its outline, and was accompanied with slight redness both of the skin and of the conjunctivæ. There was some tenderness on pressure. The patient was suffering from a specific skin affection, and, though he denied it, there was otherwise good reason for believing he had suffered from syphilis. In this case the results of treatment were exceedingly satisfactory, as the tumour quickly disappeared under the influence of blue pill and potassium iodide.

Tumours.—The lacrymal gland is liable to tumours of various kinds, some being of a malignant, others of a benign, nature. Mr. Savory[13] has described a case of tumour, probably of a malignant type, connected with the lacrymal gland, in a man aged seventy-eight. It had lasted for two years and a half from the time when chemosis first occurred, till it had developed to the size of an egg and protruded from the orbit, pushing aside and concealing the globe. On examination after death the eye was found near the centre of the mass, which, from the description given, appears to have been of the nature of what would now be called round-celled sarcoma. The lacrymal gland was not discoverable. In this, as in many other similar cases, it is difficult to determine whether the gland was primarily or secondarily attacked.

Harlan,[14] of Philadelphia, describes a case of sarcoma of the gland in a man aged seventy. The tumour was as large as an egg, and projected from the outer part of the right upper eyelid. It had been noticed for four years. The lid was closed, and the globe was immovable, and dislocated downwards and forwards. No pain had been experienced, and the health was otherwise good. After extirpation of the tumour it was found to be an enlarged lacrymal gland, and microscopical examination showed that it was a sarcoma.

Mollière and Chandelux[15] describe a case in which a peculiar form of epithelioma was presented, to which they have applied the term "intra-acinous colloid epithelioma." The patient was only fifteen years of age. Pain and swelling without obvious cause were observed. The globe was pushed to one side by the growth of the tumour. The mass was extirpated, and cicatrisation was complete in eight days. Recurrence of the growth occurred at the end of nine months, and again at the end of ten months. The tumour penetrated deeply into the orbit, and the pre-auricular ganglion was affected. No further operation was performed, and the tumour slowly enlarged in size. An examination of the tumour showed that it was intra-acinous and of the nature of an epithelioma.

White[16] has recently recorded the successful removal of a tumour of the lacrymal gland, which he has named, from its histological characters, "myxo-adeno-sarcoma." It occurred in a woman aged sixty, and had been growing for a year. The globe was pressed downwards, and was inflamed. The left disc was reddened, and vision reduced to $\frac{2}{10}$. It was removed by an incision made along the outer third of the left orbit, and was firmly attached to the periosteum and conjunctiva. It measured an inch and a quarter in length and three-quarters of an inch broad. A drainage-tube was inserted for a few days, and in three weeks it had entirely healed. Histological examination showed connective tissue variable in amount in different parts; cells also irregularly distributed; the characteristic form of myxomatous tissue in abundance in all parts; and, lastly, cylinders and alveoli lined with cells in the characteristic arrangement of adenoma.

To these may be added a remarkable case of cartilaginous tumour of the lacrymal gland which occurred in September, 1873, in St. Bartholomew's Hospital, under the care of Mr. Vernon. When admitted the patient presented a hard, well-defined, elastic tumour at the outer and upper part of the left orbit. The vision of the left eye was reduced to $\frac{1}{200}$. The tension was somewhat less than normal. The conjunctiva was congested, and there was optic neuritis. Mr. Vernon removed the tumour easily by an incision made parallel to and just below the orbital border. A month after the operation there was ptosis with some optic neuritis. The eye, which had previously been considerably depressed, had nearly recovered its normal position, and the vision had improved to $\frac{1}{10}$. The superior and external recti remained inefficient. An examination of the tumour showed that the gland was invaded or pervaded by a cartilaginous growth. It is now preserved in the museum of the hospital.

A similar case has been reported by Mr. Todd in the Dublin Hospital Reports, and one by Dr. O'Beirne. In the former the tumour had lobes, with deep fissures between them, and contained cartilaginous cysts filled with glairy fluid, the interspaces containing a firm fatty substance traversed by a fine membranous band. In Dr. O'Beirne's case the surface of the tumour was granular, and the interior of the gland was occupied with cartilage, from which septa passed to the circumference.

Becker[17] expressed the opinion that all those forms of tumour of the lacrymal gland named simple hypertrophy, adenoma, adenoid, colloid sarcoma, myxoma, fungus medullaris, and encephaloid cancer, were but different stages of the same morbid growth. He thought they all commenced as adenomas, and that the forms of degeneration above named were subsequent changes. Some cases that have been reported seem to support this view. Thus Arlt[18] gives a case of adenoma of the gland which before coming under his care had been twice removed. On being cut into it proved to be of soft consistence, and was removed piecemeal. Sections showed anastomosing hollow cell cylinders traversing a light tissue consisting of fibrillæ, long spindle cells, stellate cells, and a few round cells. Some months after the removal symptoms occurred which appeared to show that a tumour had formed in the cranial cavity, and therefore rendering it probable that it had really been a malignant tumour.

The removal of the lacrymal gland, as M. Badal,[19] of Bordeaux, has recently observed in an elaborate paper on this subject, may be undertaken for various reasons: sometimes on account of disease of its substance, or of the presence of some tumour surrounding or invading it; sometimes to open a path to the deeper parts of the orbit with as little damage to the subsequent movements of the eye as possible; lastly, it may be performed with the express object of abolishing its secretion and of freeing the patient from the discomfort of a constant overflow of tears, which he believes to be often due to the reflexly-excited excessive secretion of this gland. The anatomical disposition of the parts is of considerable importance. If, as Gosselin and Tillaud believe, the canals of the orbital and palpebral portions are distinct and independent, the removal of the portion implicated will effect a cure; but if the ducts of these parts intercommunicate, as Sappey maintains, then the extirpation of a portion of the gland will prove both unsatisfactory and ineffective. Badal reports the particulars of a very interesting case, in which in consequence of disease ectropion of the upper left lid had taken place, exposing the ducts of the gland, which numbered from eighteen to twenty. The plan adopted by Zachariah Lawrence to remove the gland was to make an incision extending along the outer third of the margin of the orbit, just below the eyebrow. Halpin, in order to avoid the presence of a cicatrix, shaved the eyebrow and then depressed the skin, making the incision follow the line of the orbital border. Tillaux (and I here quote from the recent paper on this subject by Badal[20]), drawing attention to the fact that the fibrous investment of the gland is formed above by the periosteum, recommends

that the operator, after having divided the soft parts as far as the orbital border, should cut through the periosteum at this point, separate it from the upper wall of the orbit, and then depress it in order to penetrate into the orbit. The granules of the lacrymal gland immediately come into view through the attenuated periosteum, and can be extirpated with facility. There would seem, however, to be some danger of causing necrosis of the bone by this proceeding, apart from the possible fracture of the superior wall of the orbit and injury to the gland, which at this point is sufficiently thin.

In all these methods the section is made through the skin, but Velpeau pursued another plan. He divided the external commissure, reverted the upper lid, and cut through the conjunctiva at the level of the oculo-palpebral fold. The drawback to the several plans in which the skin is divided is the likelihood of injury to the levator palpebræ superioris, and consequent ptosis, or to the external rectus, and even to the temporal artery. Once exposed, it is easy to plunge a hook into the substance of the gland and enucleate it with a few touches of a scalpel or with the curved scissors. Badal considers Velpeau's plan decidedly the best. The cut, when the lid is replaced, is remote from the surface, and it is only necessary to place a suture at the external commissure to prevent deformity. The hæmorrhage is usually trifling, and can be stopped by cold and slight pressure; it may, however, be troublesome, and in that case the clot should be cleared out and an attempt made to seize and twist the lacrymal artery. Suppuration is rare.

It must be remembered that both in Tillaud's and in Z. Lawrence's method, care must be taken to avoid injury to the levator palpebræ, as ptosis has been known to occur; and it has been thought necessary to caution the operator against inflicting injury upon either the external rectus or the temporal artery. Badal greatly prefers Velpeau's method, which, he says, has enabled him to remove many tumours from the orbit with facility; and he has had no instance under his care of vicious cicatrisation of the wound. He considers that union by the first intention is the rule.

The formation of calcareous masses or dacryoliths has, as might be expected, been very rarely observed. Schirmer[21] only mentions two cases. Samelsohn is the first who has demonstrated the fact anatomically. In an infant aged three months and a half, whose left eye watered, the anterior lobule of the lacrymal gland was found to be hypertrophied, of a bluish-red colour, and presented a concretion at the bottom of a cup-shaped depression of a brilliant white colour firmly embedded in the tissue of the gland, and which, when extracted with forceps, weighed six milligrammes. A micrographic and microchemical investigation made by Bodewig satisfied Samelsohn that such concretions do not proceed from the precipitation of the salts of the tears alone, but that there is a true neoplasia, which, being rich in lime, carbonates, and phosphates, leads to calcification and ossification (osteo-chondroma).

Velpeau enumerates the following cases in which extirpation of the gland had been performed in or before his time:—Spry, Daviel, and Guérin (*Bull. des Sci. Méd.*, t. xix, p. 64); then those of Warner, Schmidt, Beer, Rudthorfer, Travers, Mackenzie, Todd, and O'Beirne (*Archiv. Gén. de Méd.*, Janv. 1831, p. 84); Duval de Rennes ("Roux Mélanges," p. 160), and Lawrence (THE LANCET, 1828, vol. ii., p. 410). The treatment he adopts or recommends to be adopted in cases of acute inflammation of the gland is certainly exceedingly active, consisting in bleeding once, twice, or three times from the arm, the daily application of from fifteen to thirty leeches to the temple, and the local application of either cold compresses or hot poultices; if such vigorous measures cannot be borne, at a later period recourse may be had to purgatives, to counter-irritation, and mercurial inunction to the brow and temple. If an abscess forms, it should be opened as soon as possible. Velpeau states that he has met with three cases in each of which a large abscess formed within six days.

Whether the secretion of the gland undergoes material alterations in disease has not been satisfactorily determined. It is certain that in some cases the tears may long continue to flow over the cheeks as a consequence of obstructed ducts without materially reddening the skin; and, on the other hand, the tears might almost be regarded as possessing in some instances an acrid quality, as they redden and excoriate the surface of the cheek over which they run.

Clinical Lecture
ON
A CASE OF ALCOHOLIC PARAPLEGIA.

Delivered at the General Hospital, Birmingham.

BY ROBERT SAUNDBY, M.D. EDIN.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—The subject of my lecture this morning is a married woman, aged twenty-eight, who was admitted into Ward X on Feb. 8th, suffering from paralysis of the lower extremities. Her medical attendant, Mr. Proffitt of Burton, has kindly furnished me with the following valuable notes of her previous history.

He writes: "I have known Mrs. Y—— for about six years. During the first two years she lived in a private house, and during 1881, 1882, and 1883 her confinements were about all I had to attend her for. On May 19th, 1884, I was called to see her and her husband in the night. They had been thrown out of a trap. She was suffering from a bad sprain of the left ankle and knee, with some bruising of the calf and a rather bad scalp wound. She had then been for some time the landlady of a small public-house. The scalp wound took a month to heal, and she had a sharp attack of synovitis of the knee-joint. The ankle-joint gave a good deal of trouble, the bone becoming a good deal thickened, for which it was treated with Scott's dressing, and it would, I think, be the end of July, 1884, before she began to get about again with a limp. After a time she got well of that, but there was still a good deal of thickening and pain left. Shortly after the injury there was a great *deal of contraction of the muscles of the calf, drawing up the heel*, and accompanied by considerable pain. After ceasing to attend her for the above I was called upon occasionally to prescribe, and the impression gradually forced itself on my mind that she was becoming addicted to drink. She has never, however, had an attack of delirium tremens. It was in August, 1885, that the trouble with her legs began. After a visit to the seaside she called me in, complaining of pain and of loss of power in the legs, being only able to get about with assistance or by clinging to the furniture. Her memory was bad, her temper irritable, and she was *constantly drinking spirits*. She had changed a good deal in appearance, and was much wasted. From this time to the 27th of October her legs got worse, and on that date I saw her in consultation with Dr. W. Lowe, of this town. We found one leg more wasted than the other; sensation diminished in the skin in some parts, about normal in others; and great tenderness in the muscles on pressure. She could not use her legs at all, and had to be carried about in a chair. Shortly after Dr. Lowe's visit the contraction of the knee-joints came on; and her bowels, which had not given any trouble before, became very torpid, necessitating the removal of a mass of hardened fæces. *Her drinking habits continued, and were very bad.* About the time of Dr. Lowe's visit there had been some numbness and pain in one hand, and some startings and twitchings in the legs. From that time she has remained about the same; if anything, a little improvement has taken place." Mr. Proffitt adds in a postscript, "From the first it seemed to me that the muscles of the anterior part of the leg and thigh were the most affected with paralysis. She could not get her toe off the ground, and she could not kick; but she could, and I think she can now, flex the leg on the thigh and use the muscles of the calf."

I will not repeat the details of the previous history as gathered by us, except to note that her previous health had been good with the exception of scarlatina and an abscess behind the ear when a child, and that she attributes the onset of the paralysis to a chill caught while staying too long in the sea at Llandudno. The next day, she says, she had pains in the feet and toes, and walked with difficulty. She never was hysterical or nervous. Menstruation stopped after the visit to Llandudno, and did not return till ten days before admission, when she was again unwell. She was very sick for the first two months. Her father is alive, but rheumatic; her mother and all her brothers and sisters are alive and well. She tells us that there has been no instance of
